Regulation 3.2

The Walter and Eliza Hall Institute of Medical Research

AUSTRALIA

Patents Act 1990

PROVISIONAL SPECIFICATION

for the invention entitled:

"A novel phosphoprotein"

The invention is described in the following statement:

A NOVEL PHOSPHOPROTEIN

BACKGROUND OF THE INVENTION

FIELD OF THE INVENTION

The present invention relates generally to cancer therapy and cancer diagnostics and to agents useful therefor. More particularly, the present invention provides a novel tumorigenesis-related phosphoprotein and a nucleic acid molecule encoding same. The present invention also provides diagnostic agents to detect the presence or absence of the tumorigenesis-related phosphoprotein or the presence or absence of an expressible tumorigenesis-related gene encoding the phosphoprotein. Such diagnostic agents are useful in determining the likelihood of development of a tumor in a vertebrate animal such as mammal and, in particular, a human. The diagnostic agents provided by the present invention may be used *inter alia* in screening and/or predicting the likelihood of development of neoplastic diseases such as but not limited to mammary cancer.

DESCRIPTION OF THE PRIOR ART

20 Bibliographic details of the publications referred to by author in this specification are collected at the end of the description.

Reference to any prior art in this specification is not, and should not be taken as, an acknowledgment or any form of suggestion that this prior art forms part of the common

25 general knowledge in any country.

The increasing sophistication of recombinant DNA technology is greatly facilitating research and development in the medical and allied health industries. This is particularly the case in relation to genetic and immunologically based diagnostic assays for disease

30 conditions or for determining the propensity for disease conditions to develop.

The genetic bases behind cancer initiation and development are complex and generally involve a network of multiple dominant, positive regulators of oncogenesis (i.e. oncogenes) as well as multiple negative regulators, sometimes referred to as tumor suppressor genes, including, for example, transcription factors and cell-cycle regulators.

The genetic complexity of tumor initiation and development requires that further research be conducted to enable the generation of a comprehensive library of oncogenes and tumor suppressor genes to enable a full diagnosis or therapeutic regimen to be implemented. This is particularly the case since it is considered unlikely that a mutation in a single gene will prove to be responsible for the development of all tumors.

The receptor tyrosine kinase ErbB2 was first identified as the mammalian counterpart of the v-erbB oncogene and belongs to the family of ErbB receptors, comprising four members (HER1/EGFR (epidermal growth factor receptor), HER2/ErbB2/Neu,

15 HER3/ErbB3 and HER4/ErbB4). These receptors signal cooperatively by forming ligand-induced combinations of homo- and heterodimers. Over-expression of ErbB1 and ErbB2 is associated with a variety of human cancers. Of particular significance are the amplification and/or over-expression of ErbB2 in up to 30% of human breast cancer patients, in which it correlates with poor prognosis.

20 The importance of the ErbB2 signaling in mammary tumorigenesis has been established using mouse models. Over-expression of Neu, driven off the mouse mammary tumor virus promoter, induced focal mammary tumors which frequently metastasized to the lung (Guy et al., Proc. Natl. Acad. Sci. USA 89: 10578-10582, 1992). The long latency period,

25 however, suggested that additional molecular events were required for tumors to develop. Further analysis of these tumors identified somatic mutations in *neu*, resulting in constitutive activation of the receptor. The up-regulation of the ErbB3 protein concomitant with an increase in ErbB3 tyrosine phosphorylation in these tumors suggested that ErbB2 synergizes with ErbB3 in oncogenesis. The ErbB2/ErbB3 heterodimer has been shown to

30 promote efficient activation of the PI3K pathway, a pathway essential for cell proliferation and survival. However, other kinases implicated in tumorigenesis such as Src and Erk are

also activated downstream of this ErbB heterodimer. Although downstream targets of ErbB signaling have been characterized, the crucial molecular players with regard to Neu-induced transformation, specifically transcription factors that execute the signals received, remain elusive.

5

The ability to detect tumors or a likelihood or predisposition of development of a tumor would be of great benefit in terms of patient care and initiating anti-tumor therapy at an early stage.

10 The regulation of the FoxO subgroup of forkhead transcription factors, consisting of forkhead (FKH) transcription factors R (FKHR), RL1 (FkHL1) and AFX has been recently identified as being *via* the PI3K pathway. These proteins drive the expression of cell cycle regulators, such as p27 and apoptotic proteins including Bim and Fas ligand.

15 Phosphorylation on specific serine and threonine residues by phosphokinase B (PKB) leads to their inactivation and sequestration in the cytoplasm by 14-3-3 scaffolding proteins, thereby preventing their negative control on cell proliferation.

In accordance with the present invention, a novel 35kD phosphoprotein has been identified which is specifically recognized by a phospho-FKHR antibody. It is proposed that the

20 novel protein is a useful diagnostic and prognostic target for cancer as well as being a validated drug target.

SUMMARY OF THE INVENTION

Throughout this specification, unless the context requires otherwise, the word "comprise", or variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated element or integer or group of elements or integers but not the exclusion of any other element or integer or group of elements or integers.

Nucleotide and amino acid sequences are referred to by a sequence identifier number (SEQ ID NO.). The SEQ ID NOs correspond numerically to the sequence identifiers <400>1,

10 (SEQ ID NO:1), <400>2 (SEQ ID NO:2), etc. A summary of the sequence identifiers is provided in Table 1. A sequence listing is provided at the end of the specification.

The aberrant expression of the ErbB2 (also known as HER2 and Neu) receptor tyrosine kinase, implicated in the pathogenesis of a high proportion of sporadic breast cancers, was investigated. Targeted expression of ErbB2 to the mammary gland in mice leads to tumor development. A long latency period, however, suggested that additional molecular alterations were acquired during the transformation process. A novel phosphoprotein, referred to herein as "FORS" (Forkhead Related Serine) was identified as being up-regulated at the mRNA level in Neu tumors and in human breast carcinoma cell lines. The 20 gene (including cDNA) encoding FORS is referred to herein as "*Fors*".

It is proposed, in accordance with the present invention, that alterations in the FORS protein, the *Fors* gene or the expression of the *Fors* gene facilitates development of, or otherwise predisposes a subject to, the development of a tumor and in particular a 25 mammary tumor. The term "tumor" includes all forms of cancer including sarcomas and carcinomas. The present invention further relates to the treatment or prophylaxis of a tumor and in particular breast cancer by the application of genetic therapy or the administration of proteinaceous or non-proteinaceous molecules which mimic or otherwise obviate the need for or otherwise act as agonists of *Fors* or FORS. Furthermore, *Fors* or

30 FORS or derivatives or homologs thereof, may be employed to screen for potential therapeutic agents such as from natural sources or chemical or peptide libraries.

It is further proposed, therefore, that *Fors* or FORS represents a validated drug target for modulators of *Fors* expression or FORS activity.

5 Another aspect of the present invention provides an isolated nucleic acid molecule comprising a nucleotide sequence of *Fors*. Reference to "Fors" include genomic and cDNA molecules. Such nucleic acid molecules may be useful in genetic therapy to modulate expression of genomic *Fors* and/or recombinant FORS and, in particular, to reduce or otherwise ameliorate production of FORS.

10 The present invention further provides methods of diagnosis of a tumor, and in particular a breast cancer, by detecting presence or levels of FORS and/or mutations therein, or aberrations in one or both alleles of the *Fors* gene, or in the expression of one or both gene alleles. The present invention provides, therefore, diagnostic agents such as primers or

15 probes of the *Fors* gene or mutated portions thereof. The diagnostic agents of the present invention extend to immunointeractive molecules and in particular antibodies to all or antigenic parts of FORS. Such diagnostic agents are useful in the detection of a tumor or a predisposition for development of a tumor and in particular breast cancer.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 is a representation of polyacrylamide gel electrophoresis (PAGE) showing that a tumor-specific 35 kD protein cross-reacts with a phospho-FKHR antibody. (A) Mammary tumors (T) and corresponding adjacent tissue (AT) or normal mammary gland tissue (NT) from B17, C13 and B14 MMTV-Neu transgenic female were dissected, protein lysates were prepared and separated by SDS PAGE. The gel was blotted and probed with phospho-FKHR specific antibody. After stripping, the gel was re-probed with (B) ErbB2- and (C) tubulin-specific antibodies. Lysate from insulin-stimulated 293T cells, transiently 10 transfected with a FKHR expression construct, was loaded as a positive control.

Figure 2 presents diagrammatic representations showing the purification of the 35 kD protein from SKBR3 cytosol. SKBR3 cytosolic protein lysate was subjected to (A) free flow electrophoresis and (B) reverse phase HPLC as described in the Examples. The 15 fractions obtained were separated by SDS PAGE and analyzed by immunoblotting using phospho-FKHR specific antibody. In the case of RP-HPLC samples, two fractions were pooled. (C) Coomassie stain of fractions containing the 35kD protein from SKBR3 cytosolic protein lysate separated by (i) FFE, (ii) RP HPLC and (iii) 10% w/v SDS PAGE. (D) Alignment of part of the sequence of Q9Y365 (SEQ ID NO:2; band #1 in (C)) with 20 part of the sequence of FKHR1 (SEQ ID NO:3) around serine 256 (underlined), using the Dialign software.

Figure 3 provides representations indicating that FORS is a phosphoprotein and that it is highly expressed in liver. (A) Amino acid sequence of the full-length Q9Y365 (SEQ ID 25 NO:6). Peptides identified by mass spectrometry are highlighted. Methionine 68, from which translation is initiated, is indicated. In (B) and (C), 293T cells were transiently transfected with HA- or Flag-tagged *Fors*. (B) Lysates were prepared and separated by SDS PAGE and immunoblotted using phospho-FKHR specific antibody. SKBR3 protein lysate was loaded as a control. (C) FORS was immunoprecipitated with Flag antibody and 30 incubated without or with alkaline phosphatase (CIP) for 45 min at 37°C prior to separation by SDS PAGE. The gel was blotted and probed with phospho-FKHR-specific

antibody and re-probed with Flag specific antibody. 293T whole cell extract (WCE) containing transfected Flag FORS was loaded as a control. (D) A commercially available membrane (Clontech) containing poly(A)⁺ RNA from different human tissues was hybridized with a *Fors* cDNA probe.

Figure 4 provides representations of Northern analysis showing over-expression of *Fors* in breast and colon carcinoma cell lines. (A) Poly(A)⁺ RNA from breast epithelial and (B) 20 µg total RNA from colon carcinoma cell lines were hybridized with FORS and ErbB2 or EGFR cDNA probes, respectively. Equal loading was confirmed by hybridizing with a 10 GAPDH cDNA probe. Note that only 6 µg RNA was loaded in the case of SKBR3 cells.

Figure 5 presents diagrammatic representations showing FORS expression and localization using a highly specific purified peptide antibody. (A) Alignment of human Pctp (SEQ ID NO.7) and FORS (SEQ ID NO.5). The Start domain is shown in red; the peptide to which a FORS-specific antibody was raised to is highlighted in blue. In (B) and (C), protein lysates of cell lines or mouse liver, as indicated, were separated by SDS PAGE. Gels were immunoblotted with purified FORS-specific antibodies #419 and/or #420. In (C), membranes were re-probed with ErbB2, phospho-FKHR and tubulin specific antibodies. (D) Merged confocal microscopy images of MCF7 cells immunostained with #420 FORS-specific antibody (green) and counterstained with DAPI (blue). The control panel shows staining with secondary FITC-conjugated antibody and DAPI alone.

Figure 6 provides representations indicating the growth properties of murine fibroblasts stably expressing FORS. (A) Protein lysates of NIH3T3 and HER14 cells infected with pBabePuro and pBabeFors retroviral expression vectors, respectively, were separated by SDS PAGE and immunoblotted with Pctpl antibody. (B) 2000 cells per well (96 well plate) were plated on day 0 in duplicates in 10% v/v and 0.5% v/v serum. Cell growth was assayed by addition of MTS reagent and measurement of absorbance after 2 hours at 490 nm, as described in the Examples.

Figure 7 shows photographic representation indicating anchorage independent growth of fibroblasts expressing FORS. (A) 50,000 NIH3T3 Puro and Fors cells, and (B) and (C) 2,000 HER14 Puro and Fors cells were plated with or without 10 ng/ml EGF in a 0.35% w/v top agar. Photographs were taken 4 weeks later after staining with NBT overnight at a 5 : 2-fold magnification in (A) and a 1.5 fold magnification in (B) and (C).

A summary of sequence identifiers used throughout the subject specification is provided in Table 1.

TABLE 1***Summary of sequence identifiers***

SEQUENCE ID NO.	NAME	DESCRIPTION
1	FORS 265-277	partial amino acid sequence of the FORS phosphoprotein (ESAVAESREERMG) ¹
2	Q9Y365	partial amino acid sequence of a predicted human protein based on a comparative screen of the <i>C. elegans</i> proteome (QHADSLENIDESAVAESR) ¹
3	FKHR1	partial amino acid sequence of the transcription factor, FKHR (RRAASMDNNSKFAKSRSR) ¹
4	Fors	full-length cDNA encoding the FORS phosphoprotein
5	FORS	full-length amino acid sequence of FORS phosphoprotein
6	full Q9Y365	full-length amino acid sequence of predicted human protein Q9Y365
7	PCTP	full-length amino acid sequence of human phosphatidylcholine transfer protein PCTP

single amino acid code (see Table 2 for definitions)

Single and three letter abbreviations used throughout the specification are defined below.

TABLE 2

Single and three letter amino acid abbreviations

AMINO ACID	THREE-LETTER ABBREVIATION	ONE-LETTER SYMBOL
Alanine	Ala	A
Arginine	Arg	R
Asparagine	Asn	N
Aspartic acid	Asp	D
Cysteine	Cys	C
Glutamine	Gln	Q
Glutamic acid	Glu	E
Glycine	Gly	G
Histidine	His	H
Isoleucine	Ile	I
Leucine	Leu	L
Lysine	Lys	K

Proline	Pro	P
Serine	Ser	S
Threonine	Thr	T
Tryptophan	Trp	W
Tyrosine	Tyr	Y
Valine	Val	V
Any residue	Xaa	X

DETAILED DESCRIPTION OF THE INVENTION

The present invention provides an isolated nucleic acid molecule comprising a sequence of nucleotides encoding a tumorigenesis-related phosphoprotein. The gene of the present

invention is referred to herein as "*Fors*". The tumorigenesis-related proteinaceous expression product of *Fors* is referred to herein as FORS. The expression product may,

however, also include RNA (including spliced introns and exons) and an mRNA transcript and these are encompassed by the term "*Fors*". This term includes a gene or a cDNA

molecule. A proteinaceous product includes a polypeptide comprising two or more amino

10 acid residues. A "polypeptide" in this context includes a protein or peptide. The present invention provides isolated nucleic acid molecules corresponding to *Fors* as well as

nucleic acid primers and probes useful for detecting *Fors*, aberrations in the *Fors* gene including deletions, insertions, additions and point mutations as well as gene silencing events. The present invention further provides a means for detecting *Fors* expression

15 products including polypeptides and fragments thereof. The present invention further provides genetically modified animals having one or both alleles of *Fors* or its homolog deleted, mutated or its/their expression silenced. The present invention further provides

genetically modified animals comprising *Fors* genes introduced or deleted. Such animals

are useful animal models for testing the pathogenesis of cancer and/or for testing potential

20 anti-cancer agents:

Accordingly, one aspect of the present invention provides an isolated nucleic acid molecule comprising a sequence of nucleotides encoding or complementary to a sequence encoding the amino acid sequence set forth in SEQ ID NO:5 or SEQ ID NO:6 or an amino

25 acid sequence having at least about 40% similarity to SEQ ID NO:5 or SEQ ID NO:6 after optimal alignment.

As stated above, SEQ ID NO:5 represents a polypeptide expression product of *Fors* and is included in the term "FORS". SEQ ID NO:6 represents the amino acid sequence of a

30 predicted human protein, based on comparative screen of the *C. elegans* proteome with human EST nucleotide databases, designated herein "full Q9Y365".

FORS is proposed, in accordance with the present invention, to be a tumorigenesis-related phosphoprotein that is over-expressed in mouse mammary tumor cells and in human breast carcinoma cell lines, and is furthermore shown herein to co-operate with the ErbB/HER2 receptor in facilitating cellular transformation. The isolated nucleic acid molecule encoding the tumorigenesis-related phosphoprotein FORS is referred to herein as *Fors*. As stated above, the term "*Fors*" includes a genomic gene, a cDNA molecule and an mRNA transcript.

In a more particular aspect of the present invention, there is provided an isolated nucleic acid molecule comprising a sequence of nucleotides encoding or complementary to a sequence encoding a polypeptide capable of facilitating, increasing or otherwise promoting the development of a tumor in a vertebrate animal, said polypeptide comprising an amino acid sequence as set forth in SEQ ID NO:5 or SEQ ID NO:6 or an amino acid sequence having at least about 40% similarity to SEQ ID NO:5 or SEQ ID NO:6 after optimal alignment.

As stated above, the isolated nucleic acid molecule is referred to herein as *Fors*:

Consequently, an even more particular aspect of the present invention contemplates an isolated nucleic acid molecule comprising a nucleotide sequence or a complementary nucleotide sequence having the identifying characteristics of *Fors* including a nucleotide sequence substantially as set forth in SEQ ID NO:4 or a part or fragment thereof or a nucleotide sequence having at least about 40% similarity to SEQ ID NO:4 after optimal alignment or a nucleotide sequence capable of hybridizing to SEQ ID NO:4 its complementary form under low stringency conditions.

Reference to "*Fors*" includes a genomic DNA, cDNA or mRNA sequence comprising an open reading frame or a genomic nucleotide sequence comprising exons and optionally introns.

Reference herein to "*Fors*" includes derivatives or homologs thereof. A derivative includes

a mutant, part, fragment or portion of *Fors* as well as any fusion derivatives such as formed by the fusion of one or more nucleotide sequences to the 5' or 3' terminal portion of *Fors* or to the 5' or 3' terminal portion of a fragment of *Fors* such as an intron or exon fragment. A derivative of *Fors* includes single or multiple nucleotide substitutions, additions and/or deletions or inversions to all or part of *Fors* and also includes point mutations and cross-over events. The term "*Fors*" also includes its 5' and 3' untranslated regions including a promoter operably linked to *Fors* or a heterologous gene.

The present invention provides, therefore, an isolated nucleic acid molecule capable of directing transcription of a second nucleic acid molecule operably linked to the first mentioned nucleic acid molecule wherein said first nucleic acid molecule comprises a nucleotide sequence which is 5' of a nucleotide sequence set forth in SEQ ID NO:4 or a nucleotide sequence having at least about 40% similarity to SEQ ID NO:4 after optimal alignment or a nucleotide sequence capable of hybridizing to SEQ ID NO:4 or its complement under low stringency conditions.

In this embodiment, the first mentioned nucleic acid molecule is referred to herein as the *Fors* promoter. The *Fors* promoter may be used to direct expression of *Fors* or of a heterologous gene or cDNA molecule.

The *Fors* gene may be from an animal cell including from a mammal, insect, reptile, fish, avian species, arachnid or lower order organism such as a yeast, fungus or *C. elegans*. Most preferably, the *Fors* gene is from a mammal such as a human or other primate, livestock animal (e.g. sheep, pig, cow, donkey, horse, goat), laboratory test animal (e.g. mouse, rat, rabbit, hamster, guinea pig), a companion animal (e.g. dog, cat) or a captive wild animal. Most preferably, the *Fors* gene is from a human or mouse.

The exemplified *Fors* nucleotide sequence is of human origin and more particularly for human breast carcinoma cell line SKBR3 available from ATCC under Catalogue No. HTB30. Reference herein to "*Fors*" includes reference to the human forms of the gene

as well as homologs from other species such as *C. elegans* as well as a range of

polymorphic variants and/or splice variants.

The term "gene" is used in its broadest sense and includes cDNA corresponding to the exons of a gene. Accordingly, reference herein to a "gene" is to be taken to include:

- (i) a classical genomic gene consisting of transcriptional and/or translational regulatory sequences and/or a coding region and/or non-translated sequences (i.e. introns, 5'- and 3'- untranslated sequences); or
10. (ii) mRNA or cDNA corresponding to the coding regions (i.e. exons) and 5'- and 3'- untranslated sequences of the gene.

The term "gene" is also used to describe synthetic or fusion molecules encoding all or part of an expression product. In particular embodiments, the term "nucleic acid molecule" and 15. "gene" may be used interchangeably. The term "polynucleotide" may also be used to describe a nucleic acid molecule, nucleotide sequence and a gene.

The term "similarity" as used herein includes exact identity between compared sequences at the nucleotide or amino acid level. Where there is non-identity at the nucleotide level,

20. "similarity" includes differences between sequences which result in different amino acids that are nevertheless related to each other at the structural, functional, biochemical and/or conformational levels. Where there is non-identity at the amino acid level, "similarity" includes amino acids that are nevertheless related to each other at the structural, functional, biochemical and/or conformational levels. In a particularly preferred embodiment, 25. nucleotide and sequence comparisons are made at the level of identity rather than similarity.

Terms used to describe sequence relationships between two or more polynucleotides or 30. polypeptides include "reference sequence", "comparison window", "sequence similarity", "sequence identity", "percentage of sequence similarity", "percentage of sequence identity", "substantially similar" and "substantial identity". A "reference sequence" is at

least 12 but frequently 15 to 18 and often at least 25 or above, such as 30 monomer units, inclusive of nucleotides and amino acid residues, in length. Because two polynucleotides may each comprise (1) a sequence (i.e. only a portion of the complete polynucleotide sequence) that is similar between the two polynucleotides, and (2) a sequence that is

divergent between the two polynucleotides, sequence comparisons between two (or more)

polynucleotides are typically performed by comparing sequences of the two polynucleotides over a "comparison window" to identify and compare local regions of sequence similarity. A "comparison window" refers to a conceptual segment of typically 12 contiguous residues that is compared to a reference sequence. The comparison window

may comprise additions or deletions (i.e. gaps) of about 20% or less as compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. Optimal alignment of sequences for aligning a comparison window may be conducted by computerised implementations of algorithms (GAP, BESTFIT,

FASTA, and TFASTA in the Wisconsin Genetics Software Package Release 7.0; Genetics

Computer Group, 575 Science Drive, Madison, WI, USA) or by inspection and the best alignment (i.e. resulting in the highest percentage homology over the comparison window) generated by any of the various methods selected. Reference also may be made to the BLAST family of programs as, for example, disclosed by Altschul *et al.* (*Nucl. Acids Res.* 25: 3389, 1997). A detailed discussion of sequence analysis can be found in Unit 19.3 of

Ausubel *et al.* ("Current Protocols in Molecular Biology" John Wiley & Sons Inc, 1994-1998, Chapter 15).

The terms "sequence similarity" and "sequence identity" as used herein refer to the extent that sequences are identical or functionally or structurally similar on a nucleotide-by-

nucleotide basis or an amino acid-by-amino acid basis over a window of comparison.

Thus, a "percentage of sequence identity", for example, is calculated by comparing two optimally aligned sequences over the window of comparison, determining the number of positions at which the identical nucleic acid base (e.g. A, T, C, G, I) or the identical amino acid residue (e.g. Ala, Pro, Ser, Thr, Gly, Val, Leu, Ile, Phe, Tyr, Trp, Lys, Arg, His, Asp,

Glu, Asn, Gln, Cys and Met) occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the

window of comparison (i.e., the window.size), and multiplying the result by 100 to yield the percentage of sequence identity. For the purposes of the present invention, "sequence identity" will be understood to mean the "match percentage" calculated by the DNASIS computer program (Version 2.5 for windows; available from Hitachi Software engineering Co., Ltd., South San Francisco, California, USA) using standard defaults as used in the reference manual accompanying the software. Similar comments apply in relation to sequence similarity.

Preferably, the percentage similarity between a particular sequence and a reference sequence (nucleotide or amino acid) is at least about 50% or at least about 60% or at least about 70% or at least about 80% or at least about 90% or at least about 95% or above such as at least about 96%, 97%, 98%, 99% or greater.

Reference herein to a low stringency includes and encompasses from at least about 0 to at

least about 15% v/v formamide and from at least about 1 M to at least about 2 M salt for hybridization, and at least about 1 M to at least about 2 M salt for washing conditions.

Generally, low stringency is at from about 25-30°C to about 42°C. The temperature may be altered and higher temperatures used to replace formamide and/or to give alternative stringency conditions. Alternative stringency conditions may be applied where necessary,

such as medium stringency, which includes and encompasses from at least about 16% v/v to at least about 30% v/v formamide and from at least about 0.5 M to at least about 0.9 M salt for hybridization, and at least about 0.5 M to at least about 0.9 M salt for washing conditions, or high stringency, which includes and encompasses from at least about 31% v/v to at least about 50% v/v formamide and from at least about 0.01 M to at least about

0.15 M salt for hybridization, and at least about 0.01 M to at least about 0.15 M salt for washing conditions. In general, washing is carried out $T_m = 69.3 + 0.41 (G+C)\%$ (Marmur and Doty, *J. Mol. Biol.* 5: 109, 1962). However, the T_m of a duplex DNA decreases by 1°C with every increase of 1% in the number of mismatch base pairs (Bonner and Laskey, *Eur. J. Biochem.* 46: 83, 1974). Formamide is optional in these hybridization conditions.

Accordingly, particularly preferred levels of stringency are defined as follows: low stringency is 6 x SSC buffer, 0.1% w/v SDS at 25-42°C; a moderate stringency is 2 x SSC

buffer, 0.1% w/v SDS at a temperature in the range 20°C to 65°C; high stringency is 0.1 x SSC buffer, 0.1% w/v SDS at a temperature of at least 65°C.

A "Fors allele" refers to normal alleles of the *Fors* locus as well as alleles carrying

5 variations that may modulate an individual's predisposition to the development of a tumor and, in particular, a mammary tumour.

The terms "nucleic acids", "nucleotide" and "polynucleotide" include RNA, cDNA, genomic DNA, synthetic forms and mixed polymers, both sense and antisense strands, and

10 may be chemically or biochemically modified or may contain non-natural or derivatized nucleotide bases, as will be readily appreciated by those skilled in the art. Such modifications include, for example, labels, methylation, substitution of one or more of the naturally occurring nucleotides with an analog, internucleotide modifications such as uncharged linkages (e.g. methyl phosphonates, phosphotriesters, phosphoamidates,

15 carbamates, etc.), charged linkages (e.g. phosphorothioates, phosphorodithioates, etc.), pendant moieties (e.g. polypeptides), intercalators (e.g. acridine, psoralen, etc.), chelators, alkylators and modified linkages (e.g. α -anomeric nucleic acids, etc.). Also included are synthetic molecules that mimic polynucleotides in their ability to bind to a designated sequence via hydrogen binding and other chemical interactions. Such molecules are known

20 in the art and include, for example, those in which peptide linkages substitute for phosphate linkages in the backbone of the molecule.

The present invention further provides recombinant nucleic acids including a recombinant construct comprising all or part of the *Fors* coding and/or regulatory region. The

25 recombinant construct may be capable of replicating autonomously in a host cell.

Alternatively, the recombinant construct may become integrated into the chromosomal DNA of the host cell. Such a recombinant polynucleotide comprises a polynucleotide of

genomic, cDNA, semi-synthetic or synthetic origin which, by virtue of its origin or manipulation: (i) is not associated with all or a portion of a polynucleotide with which it is

30 associated in nature; (ii) is linked to a polynucleotide other than that to which it is linked in nature; or (iii) does not occur in nature. Where nucleic acids according to the invention

include RNA, reference to the sequence shown should be construed as reference to the RNA equivalent with U substituted for T.

Therefore, recombinant nucleic acids comprising sequences otherwise not naturally occurring are provided by the present invention. Although the wild-type sequence may be employed, it will often be altered, e.g. by deletion, substitution or insertion.

cDNA or genomic libraries of various types may be screened as natural sources of the nucleic acids of the present invention or such nucleic acids may be provided by amplification of sequences resident in genomic DNA or other natural sources, e.g. by PCR.

The choice of cDNA libraries normally corresponds to a tissue source, which is abundant in mRNA for the desired protein. Phage libraries are normally preferred but other types of libraries may be used. Clones of a library are spread onto plates, transferred to a substrate for screening, denatured and probed for the presence of desired sequences.

As used herein, the terms "Fors locus" and "Fors allele" refer to the double-stranded DNA comprising the locus, allele or region, as well as either of the single-stranded DNAs comprising the locus, allele or region.

20 As used herein, a "portion or part or fragment" of the *Fors* locus or allele is defined as having a minimal size of at least about 10 nucleotides or preferably about 13 nucleotides or more preferably at least about 20 nucleotides and may have a minimal size of at least about 40 nucleotides. This definition includes all sizes in the range of 10-40 nucleotides as well as greater than 40 nucleotides. Thus, this definition includes nucleic acids of 12, 15, 20, 25,

25 40, 60, 80, 100, 200, 300, 400, 500 or 700 nucleotides or nucleic acids having any number of nucleotides within these values (e.g. 13, 16, 23, 30, 38, 50, 72, 121, 673 etc. nucleotides) or nucleic acids having more than 700 nucleotides or any number of nucleotides between 700 and the number shown in SEQ ID NO:4. The present invention includes all novel nucleic acids having at least 10 nucleotides derived from SEQ ID NO:4.

30 or a complement or functional equivalent thereof.

"Operably linked" refers to a juxtaposition wherein the components so described are in a relationship permitting them to function in their intended manner. For instance, a promoter is operably linked to a coding sequence if the promoter effects its transcription or expression.

Large amounts of the polynucleotides of the present invention may be produced by replication in a suitable host cell. Natural or synthetic polynucleotide fragments coding for a desired fragment will be incorporated into recombinant polynucleotide constructs, usually DNA constructs, capable of introduction into and replication in a prokaryotic or

10 eukaryotic cell. Usually, the polynucleotide constructs are suitable for replication in a unicellular host, such as yeast or bacteria, but may also be intended for introduction to (with or without integration within the genome) cultured mammalian or plant or other eukaryotic cell lines. The purification of nucleic acids produced by the methods of the present invention are described, e.g. in Sambrook et al. (*Molecular Cloning: A Laboratory* 15 *Manual*, 2nd Ed., Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, 1989).

The polynucleotides of the present invention may also be produced by chemical synthesis, e.g. by the phosphoramidite method described by Beaucage and Carruthers (*Tetra. Letts.* 22: 1859-1862, 1981) or the triester method according to Matteucci et al. (*J. Am. Chem. Soc.* 103: 3185, 1981) and may be performed on commercial, automated oligonucleotide

20 synthesizers. A double-stranded fragment may be obtained from the single-stranded product of chemical synthesis either by synthesizing the complementary strand and annealing the strands together under appropriate conditions or by adding the complementary strand using DNA polymerase with an appropriate primer sequence.

25 Polynucleotide constructs prepared for introduction into a prokaryotic or eukaryotic host may comprise a replication system recognized by the host, including the intended polynucleotide fragment encoding the desired polypeptide and will preferably also include transcription and translational initiation regulatory sequences operably linked to the

30 polypeptide encoding segment. Expression vectors may include, for example, an origin of replication or autonomously replicating sequence (ARS) and expression control sequences,

a promoter, an enhancer and necessary processing information sites, such as ribosome-binding sites, RNA splice sites, polyadenylation sites, transcriptional terminator sequences and mRNA stabilizing sequences. Secretion signals may also be included, where appropriate, which allow the protein to cross and/or lodge in cell membranes or be secreted.

- from the cell. Such vectors may be prepared by means of standard recombinant techniques well known in the art and discussed, for example, in Sambrook *et al.* (1989) *supra*.

An appropriate promoter and other necessary vector sequences is selected so as to be functional in the host and may include, when appropriate, those naturally associated with

- 10 For genes. Examples of workable combinations of cell lines and expression vectors are described in Sambrook *et al.* (1989) *supra*). Many useful vectors are known in the art and may be obtained from suppliers such as Stratagene, New England Biolabs, Promega Biotech and others. Promoters such as the trp, lac and phage promoters, tRNA promoters and glycolytic enzyme promoters may be used in prokaryotic hosts. Useful yeast promoters

- 15 include promoter regions for metallothionein, 3-phosphoglycerate kinase or other glycolytic enzymes such as enolase or glyceraldehyde-3-phosphate dehydrogenase, enzymes responsible for maltose and galactose utilization and others. Vectors and promoters suitable for use in yeast expression are further described in European Patent Publication No. 0 073 675. Appropriate non-native mammalian promoters might include

- 20 the early and late promoters from SV40 (Fiers *et al.*, *Nature* 273: 113-120, 1978) or
 promoters derived from murine mammary tumor virus (MMTV), mouse tumor virus, avian
 sarcoma viruses, adenovirus II, bovine papilloma virus or polyoma. Insect promoters may
 be derived from baculovirus. In addition, the construct may be joined to an amplifiable
 gene (e.g. DHFR) so that multiple copies of the gene may be made. For appropriate

25. enhancer and other expression control sequences, see also *Enhancers and Eukaryotic Gene Expression*, Cold Spring Harbor Press, Cold Spring Harbour, New York (1983). See also, e.g. U.S. Patent No. 5,691,198.

While such expression vectors may replicate autonomously, they may also replicate by being inserted into the genome of the host cell, by methods well known in the art.

Expression and cloning vectors will likely contain a selectable marker and a gene encoding a protein necessary for survival or growth of a host cell transformed with the vector. The presence of this gene ensures growth of those host cells that express the inserts. Typical selection genes encode proteins that (a) confer resistance to antibiotics or other toxic substances, e.g. ampicillin, neomycin, methotrexate, etc., (b) complement auxotrophic deficiencies, or (c) supply critical nutrients not available from complex media, e.g. the gene encoding D-alanine racemase for *Bacillus*. The choice of the proper selectable marker will depend on the host cell and appropriate markers for different hosts are well known in the art.

10

The vectors containing the nucleic acids of interest can be transcribed *in vitro* and the resulting RNA introduced into the host cell by well-known methods, e.g. by injection (see Kubo *et al.*, *FEBS Lett.* 241: 119, 1988), or the vectors can be introduced directly into host cells by methods well known in the art, which vary depending on the type of cellular host,

15

including electroporation; transfection employing calcium chloride, rubidium chloride, calcium phosphate, DEAE-dextran, or other substances; microprojectile bombardment; lipofection; infection (where the vector is an infectious agent, such as a retroviral genome); and other methods. See generally, Sambrook *et al.* (1989) *supra*. The introduction of the polynucleotides into the host cell by any method known in the art, including *inter alia*,

20

those described above, will be referred to herein as "transfection". The cells into which have been introduced nucleic acids described above are meant to also include the progeny of such cells.

Large quantities of the nucleic acids and polypeptides (see below) of the present invention

25

may be prepared by expressing the *Fors* nucleic acids or portions thereof in vectors or other expression vehicles in compatible prokaryotic or eukaryotic host cells. The most commonly used prokaryotic hosts are strains of *E. coli*, although other prokaryotes, such as *Bacillus subtilis* or *Pseudomonas* may also be used.

30

Mammalian or other eukaryotic host cells, such as those of yeast, filamentous fungi, plant, insect or amphibian or avian species, may also be useful for production of the proteins of

the present invention. Propagation of mammalian cells in culture is *per se* well known. See Jakoby and Pastan (eds.), *Cell Culture. Methods in Enzymology*, Vol. 58, 1979 (Academic Press, Inc., Harcourt Brace Jovanovich (New York). Examples of commonly used mammalian host cell lines are VERO and HeLa cells, Chinese hamster ovary (CHO) cells, 293T and NIH3T3 cell lines, and WI38, BHK, and COS cell lines. An example of a commonly used insect cell line is SF9. However, it will be appreciated by the skilled practitioner that other cell lines may be appropriate, e.g. to provide higher expression, desirable glycosylation patterns or other features.

10 Clones are selected by using markers depending on the mode of the vector construction. The marker may be on the same or a different DNA molecule, preferably the same DNA molecule. In prokaryotic hosts, the transformant may be selected, e.g. by resistance to ampicillin, tetracycline or other antibiotics. Production of a particular product based on temperature sensitivity may also serve as an appropriate marker.

15 Prokaryotic or eukaryotic cells transformed with the polynucleotides of the present invention are useful not only for the production of the nucleic acids and polypeptides of the present invention but also, for example, in studying the characteristics of a FORS polypeptide.

20 Antisense polynucleotide sequences are particularly useful in the context of the present invention as they may prevent or diminish the expression of the *Fors* locus and, as will be appreciated by those skilled in the art, this may effect reduction or elimination of expression products from *Fors*, including *Fors* mRNA and FORS. Since FORS is over-

25 expressed in breast cancer cell lines and in mammary tumors, and is associated with the undesirable changes concomitant with cellular transformation and the development of uncontrolled proliferation, the means to ameliorate or diminish FORS may have beneficial therapeutic potential. Polynucleotide vectors, for example, containing all or a portion of the

30 *Fors* locus or other sequences from the *Fors* region (particularly those flanking the *Fors* locus) may be placed under the control of a promoter in an antisense orientation and introduced into a cell. Expression of such an antisense construct within a cell interferes

with *Fors* transcription and/or translation. Furthermore, alternative approaches to down-regulation using sense constructs, such as co-suppression and mechanisms to induce RNAi, may also be employed.

5. The present invention is particularly useful for screening compounds by using the FORS polypeptide or binding fragment thereof in any of a variety of drug screening techniques, such as those described herein and in International Publication No. WO 97/02048.

Yet another aspect of the present invention contemplates an expression product of *Fors*.

10. The expression product may be a polypeptide encoded by the open reading frame of *Fors* (i.e. see SEQ ID NO:5 or SEQ ID NO:6) or it may be an mRNA or RNA molecule spliced from an mRNA or precursor form thereof. Such RNA molecules include exons and introns. Such molecules or their corresponding DNA sequences may be useful as regulatory molecules in their own right or as diagnostic probes or primers for detecting wild-type or a mutated or deleted *Fors* gene.

Accordingly, another aspect of the present invention provides an expression product from *Fors*, said expression product selected from the list comprising:

20 (i) an amino acid sequence set forth in SEQ ID NO:5 or an amino acid sequence having at least 40% similarity to SEQ ID NO:5 after optimal alignment;

(ii) an amino acid sequence set forth in SEQ ID NO:5;

25 (iii) an amino acid sequence set forth in SEQ ID NO:6 or an amino acid sequence having at least 40% similarity to SEQ ID NO:6 after optimal alignment;

(iv) an amino acid sequence set forth in SEQ ID NO:6;

30 (v) a ribonucleotide sequence corresponding to SEQ ID NO:4 or a nucleotide sequence having at least about 40% similarity to SEQ ID NO:4 after optimal

alignment or a nucleotide sequence capable of hybridizing to SEQ ID NO:4 or its complementary form under low stringency conditions; and

- (vi) a ribonucleotide sequence corresponding to SEQ ID NO:4.

"FORS protein" or "FORS polypeptide" or specific FORS molecules from human or murine or other sources refers to a protein including a polypeptide encoded by the *Fors* locus, variants or fragments thereof. The term "polypeptide" refers to a polymer of amino acids and its equivalent and does not refer to a specific length of the product; thus,

peptides, oligopeptides and proteins are included within the definition of a polypeptide.

This term also does not refer to or exclude modifications of the polypeptide, for example, glycosylations, acetylations, phosphorylations and the like. Included within the definition are, for example, polypeptides containing one or more analogs of an amino acid (including, for example, unnatural amino acids, etc.), polypeptides with substituted linkages as well as

other modifications known in the art, both naturally and non-naturally occurring.

Ordinarily, such polypeptides will be at least about 40% similar to the natural FORS sequence, preferably in excess of 50% such as greater than 60%, 70%, 80% or 90% and more preferably at least about 95% similar. Also included are proteins encoded by DNAs which hybridize under high or low stringency conditions to *Fors*-encoding nucleic acids

and closely related polypeptides or proteins retrieved by antisera to the FORS protein.

The FORS polypeptide is shown in SEQ ID NO:5 and SEQ ID NO:6 and may be in isolated and/or purified form, free or substantially free of material with which it is naturally associated. The polypeptide may, if produced by expression in a prokaryotic cell

or produced synthetically, lack native post-translational processing, such as glycosylation.

Alternatively, the present invention is also directed to polypeptides which are sequence variants, alleles or derivatives of the FORS polypeptide. Such polypeptides may have an amino acid sequence which differs from that set forth in SEQ ID NO:5 or SEQ ID NO:6 by one or more of addition, substitution, deletion or insertion of one or more amino acids.

Conveniently, such polypeptides have FORS function but if not, they may nevertheless be useful in diagnostic or therapeutic assays.

Substitutional variants typically contain the exchange of one amino acid for another at one or more sites within the protein and may be designed to modulate one or more properties of the polypeptide such as stability against proteolytic cleavage without the loss of other

functions or properties. Amino acid substitutions may be made on the basis of similarity in polarity, charge, solubility, hydrophobicity, hydrophilicity and/or the amphipathic nature of the residues involved. Preferred substitutions are ones that are conservative, that is, one amino acid is replaced with one of similar shape and charge. Conservative substitutions are well known in the art and typically include substitutions within the following groups:

glycine; alanine; valine; isoleucine; leucine; aspartic acid; glutamic acid; asparagine, glutamine; serine, threonine; lysine, arginine; and tyrosine, phenylalanine.

Certain amino acids may be substituted for other amino acids in a protein structure without appreciable loss of interactive binding capacity with structures such as, for example,

antigen-binding regions of antibodies or binding sites on substrate molecules or binding sites on proteins interacting with the FORS polypeptide. Since it is the interactive capacity and nature of a protein which defines that protein's biological functional activity, certain amino acid substitutions can be made in a protein sequence and its underlying DNA coding sequence and nevertheless obtain a protein with like properties. In making such changes,

the hydrophobic index of amino acids may be considered. The importance of the hydrophobic amino acid index in conferring interactive biological function on a protein is generally understood in the art (Kyte and Doolittle, *J. Mol. Biol.* 157: 105-132, 1982).

Alternatively, the substitution of like amino acids can be made effectively on the basis of hydrophilicity. The importance of hydrophilicity in conferring interactive biological

function of a protein is generally understood in the art (U.S. Patent No. 4,554,101). The use of the hydrophobic index or hydrophilicity in designing polypeptides is further discussed in U.S. Patent No. 5,691,198.

The length of the polypeptide sequences compared for homology will generally be at least

about 16 amino acids, usually at least about 20 residues, more usually at least about 24 residues, typically at least about 28 residues and preferably more than about 35 residues.

The present invention further contemplates chemical analogs of the FORS polypeptide.

Analogs contemplated herein include but are not limited to modification to side chains, incorporating of unnatural amino acids and/or their derivatives during peptide, polypeptide or protein synthesis and the use of crosslinkers and other methods which impose conformational constraints on the proteinaceous molecule or their analogues.

Examples of side chain modifications contemplated by the present invention include modifications of amino groups such as by reductive alkylation by reaction with an aldehyde followed by reduction with NaBH₄; amidination with methylacetimidate; acylation with acetic anhydride; carbamoylation of amino groups with cyanate; trinitrobenzylolation of amino groups with 2, 4, 6-trinitrobenzene sulphonic acid (TNBS); acylation of amino groups with succinic anhydride and tetrahydrophthalic anhydride; and pyridoxylation of lysine with pyridoxal-5-phosphate followed by reduction with NaBH₄.

The guanidine group of arginine residues may be modified by the formation of heterocyclic condensation products with reagents such as 2,3-butanedione, phenylglyoxal and glyoxal.

The carboxyl group may be modified by carbodiimide activation via O-acylisourea formation followed by subsequent derivitization, for example, to a corresponding amide.

Sulphydryl groups may be modified by methods such as carboxymethylation with iodoacetic acid or iodoacetamide; performic acid oxidation to cysteic acid; formation of a mixed disulphides with other thiol compounds; reaction with maleimide, maleic anhydride or other substituted maleimide; formation of mercurial derivatives using 4-chloromercuribenzoate, 4-chloromercuriphenylsulphonic acid; phenylmercury chloride, 2-chloromercuri-4-nitrophenol and other mercurials; carbamoylation with cyanate at alkaline pH.

Tryptophan residues may be modified by, for example, oxidation with N-bromosuccinimide or alkylation of the indole ring with 2-hydroxy-5-nitrobenzyl bromide or sulphenyl halides. Tyrosine residues on the other hand, may be altered by nitration with tetranitromethane to form a 3-nitrotyrosine derivative.

5

Modification of the imidazole ring of a histidine residue may be accomplished by alkylation with iodoacetic acid derivatives or N-carbethoxylation with diethylpyrocarbonate.

10 Examples of incorporating unnatural amino acids and derivatives during peptide synthesis

include, but are not limited to, use of norleucine, 4-amino butyric acid, 4-amino-3-hydroxy-5-phenylpentanoic acid, 6-aminohexanoic acid, t-butylglycine, norvaline, phenylglycine, ornithine, sarcosine, 4-amino-3-hydroxy-6-methylheptanoic acid, 2-thienylalanine and/or D-isomers of amino acids. A list of unnatural amino acid contemplated

15 herein is shown in Table 3.

TABLE 3

Codes for non-conventional amino acids

5

Non-conventional amino acid	Code	Non-conventional amino acid	Code
α -aminobutyric acid	Abu	L-N-methylalanine	Nmala
10 α -amino- α -methylbutyrate	Mgabu	L-N-methylarginine	Nmarg
aminocyclopropane- carboxylate	Cpro	L-N-methyleparagine	Nmasn
aminoisobutyric acid	Aib	L-N-methyleaspartic acid	Nmasp
aminonorbornyl- carboxylate	Norb	L-N-methylcysteine	Nmcys
15 cyclohexylalanine	Chexa	L-N-methylglutamine	Nmgln
cyclopentylalanine	Cpen	L-N-methylglutamic acid	Nmglu
D-alanine	Dal	L-N-methylhistidine	Nmhis
D-arginine	Darg	L-N-methylisoleucine	Nmile
20 D-aspartic acid	Dasp	L-N-methylleucine	Nmleu
D-cysteine	Dcys	L-N-methylmethionine	Nmmet
D-glutamine	Dgln	L-N-methylnorleucine	Nmnle
D-glutamic acid	Dglu	L-N-methylnorvaline	Nmnva
D-histidine	Dhis	L-N-methylornithine	Nmorn
25 D-isoleucine	Dile	L-N-methylphenylalanine	Nmphe
D-leucine	Dleu	L-N-methylproline	Nmpro
D-lysine	Dlys	L-N-methylserine	Nmser
D-methionine	Dmet	L-N-methylthreonine	Nmthr
D-ornithine	Dorn	L-N-methyltryptophan	Nmtip
30 D-phenylalanine	Dphe	L-N-methyltyrosine	Nmtyr
D-proline	Dpro	L-N-methylvaline	Nmval
D-serine	Dser	L-N-methylethylglycine	Nmetg
		L-N-methyl-t-butylglycine	Nmtbug

D-threonine	Dthr	L-norleucine	Nle
D-tryptophan	Dtrp	L-norvaline	Nva
D-tyrosine	Dtyr	α -methyl-aminoisobutyrate	Maib
D-valine	Dval	α -methyl- γ -aminobutyrate	Mgabu
5 D- α -methylalanine	Dmala	α -methylcyclohexylalanine	Mchexa
D- α -methylarginine	Dmarg	α -methylcyclopentylalanine	Mcpen
D- α -methylasparagine	Dmasn	α -methyl- α -naphthylalanine	Manap
D- α -methylaspartate	Dmasp	α -methylpenicillamine	Mpen
D- α -methylcysteine	Dmcys	N-(4-aminobutyl)glycine	Nglu
10 D- α -methylglutamine	Dmgln	N-(2-aminoethyl)glycine	Naeg
D- α -methylhistidine	Dmhis	N-(3-aminopropyl)glycine	Norn
D- α -methylisoleucine	Dmile	N-amino- α -methylbutyrate	Nmaabu
D- α -methylleucine	Dmleu	α -naphthylalanine	Anap
D- α -methyllysine	Dmlys	N-benzylglycine	Nphe
15 D- α -methylmethionine	Dmmet	N-(2-carbamylethyl)glycine	Ngln
D- α -methylornithine	Dmorn	N-(carbamylmethyl)glycine	Nasn
D- α -methylphenylalanine	Dmphe	N-(2-carboxyethyl)glycine	Nglu
D- α -methylproline	Dmpro	N-(carboxymethyl)glycine	Nasp
D- α -methylserine	Dmser	N-cyclobutylglycine	Ncbut
20 D- α -methylthreonine	Dmthr	N-cycloheptylglycine	Nchep
D- α -methyltryptophan	Dmtup	N-cyclohexylglycine	Nchex
D- α -methyltyrosine	Dmty	N-cyclodecylglycine	Ncdec
D- α -methylvaline	Dmyal	N-cyclododecylglycine	Ncdod
D-N-methylalanine	Dnmala	N-cyclooctylglycine	Ncoct
25 D-N-methylarginine	Dnmarg	N-cyclopropylglycine	Ncpo
D-N-methylasparagine	Dnmasn	N-cycloundecylglycine	Ncund
D-N-methylaspartate	Dnmasp	N-(2,2-diphenylethyl)glycine	Nbhm
D-N-methylcysteine	Dnmcys	N-(3,3-diphenylpropyl)glycine	Nbhe
D-N-methylglutamine	Dnmgln	N-(3-guanidinopropyl)glycine	Narg
30 D-N-methylglutamate	Dnmglu	N-(1-hydroxyethyl)glycine	Nthr

D-N-methylhistidine	Dnmhis	N-(hydroxyethyl)glycine	Nser
D-N-methylisoleucine	Dnmile	N-(imidazolylethyl)glycine	Nhis
D-N-methylleucine	Dnmleu	N-(3-indolylethyl)glycine	Nhtrp
D-N-methyllysine	Dnmlys	N-methyl- γ -aminobutyrate	Nmgabu
5 N-methylcyclonexylalanine	Nmchexa	D-N-methylmethionine	Dnmmet
D-N-methylornithine	Dnmorn	N-methylcyclopentylalanine	Nmcpen
N-methylglycine	Nala	D-N-methylphenylalanine	Dnmphe
N-methylaminoisobutyrate	Nmaib	D-N-methylproline	Dnmpro
N-(1-methylpropyl)glycine	Nile	D-N-methylserine	Dnmser
10 N-(2-methylpropyl)glycine	Nieu	D-N-methylthreonine	Dnmthr
D-N-methyltryptophan	Dnmtlp	N-(1-methylethyl)glycine	Nval
D-N-methyltyrosine	Dnmtyr	N-methyl- α -naphylalanine	Nmanap
D-N-methylvaline	Dnmval	N-methylpenicillamine	Nmpen
γ -aminobutyric acid	Gabu	N-(p-hydroxyphenyl)glycine	Nhtyr
15 L- α -butylglycine	Tbug	N-(thiomethyl)glycine	Ncys
L-ethylglycine	Etg	penicillamine	Pen
L-homophenylalanine	Hphe	L- α -methylalanine	Mala
L- α -methylarginine	Marg	L- α -methylasparagine	Masn
L- α -methylaspartate	Masp	L- α -methyl- β -butylglycine	Mtbug
20 L- α -methylcysteine	Mcys	L-methylethylglycine	Metg
L- α -methylglutamine	Mgin	L- α -methylglutamate	Mglu
L- α -methylhistidine	Mhis	L- α -methylhomophenylalanine	Mhphe
L- α -methylisoleucine	Mile	N-(2-methylthioethyl)glycine	Nmet
L- α -methylleucine	Mleu	L- α -methyllysine	Mlys
25 L- α -methylmethionine	Mmet	L- α -methylnorleucine	Mnle
L- α -methylnorvaline	Mnva	L- α -methylornithine	Morn
L- α -methylphenylalanine	Mphe	L- α -methylproline	Mpro
L- α -methylserine	Mser	L- α -methylthreonine	Mthr
L- α -methyltryptophan	Mtrp	L- α -methyltyrosine	Mtyr
30 L- α -methylvaline	Mval	L-N-methylhomophenylalanine	Nmhphe

N-(N-(2,2-diphenylethyl) carbamylmethyl)glycine	Nnbhm	N-(N-(3,3-diphenylpropyl) carbamylmethyl)glycine	Nnbhe
1-carboxy-1-(2,2-diphenyl- ethylamino)cyclopropane	Nmbc		

5

Crosslinkers can be used, for example, to stabilize 3D conformations, using homo-bifunctional crosslinkers such as the bifunctional imido esters having $(CH_2)_n$ spacer groups with $n=1$ to $n=6$, glutaraldehyde, N-hydroxysuccinimide esters and hetero-bifunctional reagents which usually contain an amino-reactive moiety such as N-hydroxysuccinimide and another group specific-reactive moiety such as maleimido or dithio moiety (SH) or carbodiimide (COOH). In addition, peptides can be conformationally constrained by, for example, incorporation of C_α and N α-methylamino acids, introduction of double bonds between C_α and C_β atoms of amino acids and the formation of cyclic peptides or analogues 10 by introducing covalent bonds such as forming an amide bond between the N and C termini between two side chains or between a side chain and the N or C terminus.

The term "peptide mimetic" or "mimetic" is intended to refer to a substance, which has the essential biological activity of the FORS polypeptide. A peptide mimetic may be a peptide 15 containing molecule that mimics elements of protein secondary structure (Johnson *et al.*,

"Peptide Turn Mimetics" in *Biotechnology and Pharmacy*, Pezzuto *et al.*, Eds., Chapman and Hall, New York, 1993). The underlying rationale behind the use of peptide mimetics is that the peptide backbone of proteins exists chiefly to orient amino acid side chains in such a way as to facilitate molecular interactions such as those of antibody and antigen, enzyme and substrate or scaffolding proteins. A peptide mimetic is designed to permit molecular interactions similar to the natural molecule. A mimetic may not be a peptide at all, but it will retain the essential biological activity of natural FORS polypeptide.

The FORS polypeptide or fragment employed in a test such as a diagnostic or therapeutic assay may either be free in solution, affixed to a solid support, or borne on a cell surface.

One method of drug screening utilizes eukaryotic or prokaryotic host cells that are stably

transformed with recombinant polynucleotides expressing the polypeptide or fragment, preferably in competitive binding assays. Such cells, either in viable or fixed form, can be used for standard binding assays. One may measure, for example, the formation of complexes between a FORS polypeptide or fragment and the agent being tested, or examine the degree to which the formation of a complex between a FORS polypeptide or fragment and a known ligand is aided or interfered with by the agent being tested.

It is proposed in accordance with the present invention that tumors have a propensity to develop in subjects who have cells in which the *Fors* gene is expressed. Consequently, the diagnostic and prognostic methods of the present invention detect or assess the presence of the *Fors* gene or locus and confirm the presence of a tumor or a predisposition to the development of a tumor. Useful diagnostic techniques to detect the presence of *Fors* include but are not limited to fluorescent *in situ* hybridization (FISH), direct DNA sequencing, PFGE analysis, Southern blot analysis, single-stranded conformational analysis (SSCA), RNase protection assay, allele-specific oligonucleotide (ASO hybridization), dot blot analysis and single-stranded conformation polymorphism assay (SSCP) [Orita *et al.*, *Proc. Nat. Acad. Sci. USA* 86: 2776-2770, 1989]. Also useful is DNA microchip technology as well as electrotide. Electrotides may also be used as a detection system. Such a system relies on complementary binding of RNA or DNA to assemble an electronic circuit which thereby creates a detectable electronic signal. One particularly useful system is eSensor (trade mark; Motorola) which is well described at http://www.motorola.com/lifesciences/esensor/tech_overview.html.

Predisposition to cancers, such as mammary tumors, can be ascertained by testing any tissue of a human for the presence of an expressible *Fors* gene. For example, an individual who has inherited a germ-line *Fors* gene would be prone to develop cancers. This can be determined by testing DNA from any tissue of an individual's body. In addition, pre-natal diagnosis can be accomplished by testing foetal cells, placental cells or amniotic fluid for the presence of the *Fors* gene.

It should be pointed out that reference to a "subject", "individual", "patient" or "vertebrate"

"animal" is not to be taken as limiting the target to a particular animal or human. The present invention is applicable to detecting tumors in a range of vertebrate animals, although humans are preferred.

5 Alteration of *Fors* mRNA expression can be detected by any of a number of techniques known in the art. These include Northern blot analysis, PCR amplification, RNase protection and microchip technology. Diminished mRNA expression correlates with reduced levels of expressed FORS phosphoprotein and, consequently, increased likelihood of enhanced therapeutic outcomes. Analogously, enhanced mRNA expression correlates 10 with enhanced levels of expressed FORS phosphoprotein and, consequently, increased likelihood of the existence of or the propensity for the development of cancer and, in particular, mammary cancer. The need for intervention to deliver improved therapeutic outcomes is thereby indicated.

15 *Fors* genes can also be detected by screening for a FORS protein. For example, monoclonal and polyclonal antibodies immunoreactive with FORS can be used to screen a tissue. Presence of cognate antigen indicates existence of FORS phosphoprotein and, hence, increased chance of the existence of or the propensity for the development of cancer and, especially, breast cancer. Such immunological assays can be done in any convenient 20 format known in the art. These include Western blots, immunohistochemical assays and ELISA assays. Any means for detecting a FORS protein can be used to detect a wild-type *Fors* gene.

The use of monoclonal antibodies in an immunoassay is particularly preferred because of 25 the ability to produce them in large quantities and the homogeneity of the product. The preparation of hybridoma cell lines for monoclonal antibody production is derived by fusing an immortal cell line and lymphocytes sensitized against the immunogenic preparation (i.e. comprising FORS) or can be done by techniques which are well known to those who are skilled in the art. (See, for example, Douillard and Hoffman, *Basic Facts 30 about Hybridomas*, in *Compendium of Immunology* Vol. II, ed. by Schwartz, 1981; Kohler

and Milstein, *Nature* 256: 495-499, 1975; Kohler and Milstein, *European Journal of Immunology* 6: 511-519, 1976).

Another aspect of the present invention contemplates a method for detecting FORS in a biological sample from a subject, said method comprising contacting said biological sample with an antibody specific for FORS or its derivatives or homologs for a time and under conditions sufficient for an antibody-FORS complex to form, and then detecting said complex.

10 The presence of FORS may be accomplished in a number of ways such as by Western blotting and ELISA procedures. A wide range of immunoassay techniques are available as can be seen by reference to U.S. Patent Nos. 4,016,043, 4,424,279 and 4,018,653. These include both single-site and two-site or "sandwich" assays of the non-competitive types, as well as in the traditional competitive binding assays. These assays also include direct

15 binding of a labeled antibody to a target.

Sandwich assays are among the most useful and commonly used assays and are favoured for use in the present invention. A number of variations of the sandwich assay technique exist, and all are intended to be encompassed by the present invention. Briefly, in a typical

20 forward assay, an unlabeled antibody is immobilized on a solid substrate and the sample to be tested brought into contact with the bound molecule. After a suitable period of incubation, for a period of time sufficient to allow formation of an antibody-antigen complex, a second antibody specific to the antigen, labeled with a reporter molecule capable of producing a detectable signal is then added and incubated, allowing time
25 sufficient for the formation of another complex of antibody-antigen-labeled antibody. As stated above, the antigen is FORS or a fragment thereof. Any unreacted material is washed away, and the presence of the antigen is determined by observation of a signal produced by the reporter molecule. The results may either be qualitative, by simple observation of the visible signal, or may be quantified by comparing with a control sample containing known

30 amounts of hapten. Variations on the forward assay include a simultaneous assay, in which both sample and labeled antibody are added simultaneously to the bound antibody. These

techniques are well known to those skilled in the art, including any minor variations as will be readily apparent. In accordance with the present invention, the sample is one which might contain FORS including cell extract or tissue biopsy. As FORS is an intracellular molecule, cell extracts and in particular cytoplasmic extracts are preferred. The sample is, therefore, generally a biological sample comprising biological fluid.

In a typical forward sandwich assay, a first antibody having specificity for the FORS or antigenic parts thereof, is either covalently or passively bound to a solid surface. The solid surface is typically glass or a polymer, the most commonly used polymers being cellulose,

10 polyacrylamide, nylon, polystyrene, polyvinyl chloride or polypropylene. The solid supports may be in the form of tubes, beads, discs or microplates, or any other surface suitable for conducting an immunoassay. The binding processes are well known in the art and generally consist of cross-linking covalently binding or physically adsorbing, the polymer-antibody complex to the solid surface, which is then washed in preparation for the

15 test sample. An aliquot of the sample to be tested is then added to the solid phase complex and incubated for a period of time sufficient (e.g. 2-40 minutes or overnight if more convenient) and under suitable conditions (e.g. from room temperature to about 37°C including 25°C) to allow binding of any sub-unit present in the antibody. Following the incubation period, the antibody sub-unit-solid phase is washed and dried and incubated

20 with a second antibody specific for a portion of the antigen. The second antibody is linked to a reporter molecule, which is used to indicate the binding of the second antibody to the antigen.

An alternative method involves immobilizing the target molecules in the biological sample

25 and then exposing the immobilized target to specific antibody, which may or may not be labeled with a reporter molecule. Depending on the amount of target and the strength of the reporter molecule signal, a bound target may be detectable by direct labeling with the antibody.

Alternatively, a second labeled antibody, specific to the first antibody is exposed to the target-first antibody complex to form a target-first antibody-second antibody tertiary complex. The complex is detected by the signal emitted by the reporter molecule.

5 By "reporter molecule" as used in the present specification, is meant a molecule which, by its chemical nature, provides an analytically identifiable signal which allows the detection of antigen-bound antibody. Detection may be either qualitative or quantitative. The most commonly used reporter molecules in this type of assay are enzymes, fluorophores or radionuclide-containing molecules (i.e. radioisotopes) and chemiluminescent molecules.

10 In the case of an enzyme immunoassay, an enzyme is conjugated to the second antibody, generally by means of glutaraldehyde or periodate. As will be readily recognized, however, a wide variety of different conjugation techniques exist, which are readily available to the skilled artisan. Commonly used enzymes include horseradish peroxidase, glucose oxidase,

15 β -galactosidase and alkaline phosphatase, amongst others. The substrates to be used with the specific enzymes are generally chosen for the production, upon hydrolysis by the corresponding enzyme, of a detectable color change. Examples of suitable enzymes include alkaline phosphatase and peroxidase. It is also possible to employ fluorogenic substrates, which yield a fluorescent product rather than the chromogenic substrates noted

20 above. In all cases, the enzyme-labeled antibody is added to the first antibody hapten complex, allowed to bind, and then the excess reagent is washed away. A solution containing the appropriate substrate is then added to the complex of antibody-antigen antibody. The substrate will react with the enzyme linked to the second antibody, giving a qualitative visual signal, which may be further quantified, usually spectrophotometrically,

25 to give an indication of the amount of hapten which was present in the sample. "Reporter molecule" also extends to use of cell agglutination or inhibition of agglutination such as red blood cells on latex beads, and the like.

30 Alternately, fluorescent compounds, such as fluorescein and rhodamine, may be chemically coupled to antibodies without altering their binding capacity. When activated by illumination with light of a particular wavelength, the fluorochrome-labeled antibody

absorbs the light energy, inducing a state to excitability in the molecule, followed by emission of the light at a characteristic color visually detectable with a light microscope.

As in the EIA, the fluorescent-labeled antibody is allowed to bind to the first antibody-hapten complex. After washing off the unbound reagent, the remaining tertiary complex is then exposed to the light of the appropriate wavelength; the fluorescence observed indicates the presence of the hapten of interest. Immunofluorescence and EIA techniques are both very well established in the art and are particularly preferred for the present method. However, other reporter molecules, such as radioisotope, chemiluminescent or bioluminescent molecules, may also be employed.

10

The present invention is predicated in part on the determination that aberrant cells and in particular cancer cells and even more particularly mammary cancer cells or cells with a propensity for developing into mammary cells express elevated levels of FORS relative to normal cells. FORS is a phosphoprotein, which is demonstrated herein to be associated

15

with *inter alia* cellular transformation. Moreover, its over-expression correlated with the up-regulation of the ErbB/HER2 receptor, over-expression of which in 30% of human breast cancer cases is known to be associated with poor prognosis. Hence, a cell that produces high levels of the FORS protein is deemed, in accordance with the present invention, to be an aberrant cell and a cell associated with or likely to be associated with a disease such as cancer and, in particular, mammary cancer. The ability to detect FORS, or expression products of genetic material *Fors* which encodes FORS, provides a means for detecting or diagnosing cancer or a propensity for the development of cancer.

20

Accordingly, in another aspect, the present invention contemplates a method for detecting an aberrant cell in a subject or in a biological sample from said subject, said method comprising contacting cells or cell extracts from said subject or said biological sample with an immunointeractive molecule specific for FORS or an antigenic portion thereof and screening for the level of immunointeractive molecule-FORS complex formations wherein an elevated presence of said complex relative to a normal cell is indicative of an aberrant

25

cell.

In a related embodiment, the present invention provides a method for detecting an aberrant cell in a subject or in a biological sample from said subject, said method comprising screening the level of an expression product of a gene encoding a FORS, wherein an elevated level of said expression product compared to a normal cell is indicative of an aberrant cell.

A "biological sample" from a subject includes a biopsy and may be any sample of cells, cell extract, tissue, tissue fluid, excretia, circulatory fluid or respiratory fluid or other material. The biological sample may be extracted, treated, untreated, diluted or concentrated from the subject.

Reference to a "normal" cell includes a cell not regarded as aberrant or cancerous and may be considered an "average" of normal cell types.

The "immunointeractive molecule" is any molecule having specificity and binding affinity for FORS or its antigenic parts or its homologues or derivatives. Although the preferred immunointeractive molecule is an immunoglobulin molecule, the present invention extends to other immunointeractive molecules such as antibody fragments, single chain antibodies, de-immunized including humanized antibodies and T-cell associated antigen-binding molecules (TABMs). Most preferably, the immunointeractive molecule is an antibody such as a polyclonal or monoclonal antibody. Most preferably, the antibody is a monoclonal antibody.

The immunointeractive molecule exhibits specificity for FORS or more particularly an antigenic determinant or epitope on FORS. An antigenic determinant or epitope on FORS includes that part of the molecule to which an immune response is directed. The antigenic determinant or epitope may be a B-cell epitope or where appropriate a T-cell epitope. The term "antigenic part" includes an antigenic determinant or epitope.

As described above, an "expression product" may be an mRNA or cDNA and the amount of expression product provides an indicator of the level of *Fors* gene expression and

provides, therefore, indirect evidence for the presence of FORS protein. Conveniently, pools of mRNA or cDNA are obtained or cell extracts comprising total mRNA obtained and genetic probes complementary to all or part of the *Fors* gene-specific mRNA or cDNA. Binding of probes may then be quantified or semi-quantified.

Reference to a "level" of FORS includes an amount quantitatively, semi-quantitatively or qualitatively determined.

In accordance with the present invention, it is proposed that cells associated with a cancer and in particular mammary cancer cells produce elevated levels of FORS. The quantitative or qualitative detection of levels of FORS or expression products of genetic material encoding FORS provides, therefore, an indicator that the cell is aberrant and is associated with cancer or has a propensity to develop into a cancer.

Accordingly, another aspect of the present invention contemplates a method for diagnosing the presence of cancer or cancer-like growth in a subject, said method comprising contacting cells or cell extracts from said subject or a biological sample from said subject with a FORS-binding effective amount of an antibody having specificity for said FORS or an antigenic determinant or epitope thereon and then quantitatively or qualitatively determining the level of a FORS-antibody complex wherein the presence of elevated levels of said complex compared to a normal cell is indicative of the presence of a cancer.

In a related embodiment, the present invention provides a method for diagnosing the presence of a cancer in a subject, said method comprising obtaining mRNA from cells of said subject or from a biological sample from said subject and optionally generating cDNA and contacting said mRNA or cDNA with a genetic probe capable of hybridizing to and/or amplifying all or part of a *Fors* nucleotide sequence encoding FORS or its complementary nucleotide sequence and then detecting the level of said mRNA or cDNA wherein the presence of elevated levels of said mRNA or cDNA compared to normal controls is indicative of the presence of cancer.

The use of antibodies and, in particular, monoclonal antibodies to detect FORS is the preferred method for use in this aspect of the present invention. Antibodies may be prepared by any of a number of means, as have been described above.

5 The present invention further contemplates the use of competitive drug screening assays, in which neutralizing antibodies capable of specifically binding the FORS polypeptide compete with a test compound for binding to the FORS polypeptide or fragments thereof. In this manner, the antibodies can be used to detect the presence of any peptide that shares one or more antigenic determinants of the FORS polypeptide. Such screening methods are not limited to assays employing only FORS, but are also applicable to studying FORS protein complexes. The effect of drugs on the activity of this complex is analyzed.

Following identification of a substance that modulates or affects polypeptide activity, the substance may be investigated further. Furthermore, it may be manufactured and/or used in preparation, i.e. manufacture or formulation or a composition such as a medicament, pharmaceutical composition or drug. These may be administered to individuals in a method of treatment or prophylaxis.

10 The identification of FORS as a tumorigenesis-related molecule permits the generation of targeting agents to destroy or at least retard the growth of the cancer cells. In particular, the cancer targeting agents comprising FORS-specific antibodies are fused, bound or otherwise associated with a cell growth inhibiting or killing agent. Such agents include but are not limited to cytoidal or cytostatic agents which act at the protein or corresponding mRNA or DNA levels. For example, the cell growth or killing agent maybe a nuclear tag 15 or may be an agent which promotes induction of antagonists of FORS RNAi or RNA oligonucleotides.

Accordingly, another aspect of the present invention contemplates a method for the treatment of a patient having cancer, said method comprising administering to said human, 20 a cancer cell growth inhibiting-effective amount of an antibody having specificity for human FORS protein, wherein said antibody is substantially non-immunogenic and further

comprises a cell growth inhibiting or cell killing agent fused, bound or otherwise associated thereto.

The present invention further contemplates compositions comprising the cancer targeting

agents of the present invention and one or more pharmaceutically acceptable carriers

and/or diluents. The pharmaceutical forms suitable for injectable use include sterile aqueous solutions. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dilution medium comprising, for example, water,

ethanol, polyol (for example, glycerol, propylene glycol and liquid polyethylene glycol, and the like), suitable mixtures thereof and vegetable oils. The proper fluidity can be maintained, for example, by the use of surfactants. The prevention of the action of microorganisms can be brought about by various anti-bacterial and anti-fungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, thimerosal and the like. In many

cases, it will be preferable to include isotonic agents, for example, sugars or sodium chloride. Prolonged absorption of the injectable compositions can be brought about by the use in the compositions of agents delaying absorption, for example, aluminium monostearate and gelatin.

20. Sterile injectable solutions are prepared by incorporating the active compounds in the required amount in the appropriate solvent with the active ingredient and optionally other active ingredients as required, followed by filtered sterilization or other appropriate means of sterilization.

25. Pharmaceutically acceptable carriers and/or diluents include any and all solvents, dispersion media, coatings, anti-bacterial and anti-fungal agents, isotonic and absorption delaying agents and the like. The use of such media and agents for pharmaceutical active substances is well known in the art and except insofar as any conventional media or agent is incompatible with the active ingredient, their use in the therapeutic compositions is contemplated.

30. Supplementary active ingredients can also be incorporated into the compositions.

The active agent is preferably administered in a therapeutically effective amount. The actual amount administered and the rate and time-course of administration will depend on the nature and severity of the condition being treated. Prescription of treatment, e.g.

5 decisions on dosage, timing, etc. is within the responsibility of general practitioners or specialists and typically takes account of the disorder to be treated, the condition of the individual patient, the site of delivery, the method of administration and other factors known to practitioners. Examples of techniques and protocols can be found in Remington's Pharmaceutical Sciences, 18th Ed. (Mack Publishing Company, Easton, PA, U.S.A., 1990).

10

Thus, the present invention extends to a pharmaceutical composition, medicament, drug or other composition comprising FORS, a fragment thereof or a FORS antagonist or mimetic thereof, or a FORS-specific antibody, associated with a cell growth inhibiting or killing agent, a method comprising administration of such a composition, a method comprising administration of such a composition to a patient, e.g. for treatment (which may include preventative treatment) of cancer, use of such a composition in the manufacture of a composition for administration, e.g. for treatment of cancer, and a method of making a pharmaceutical composition comprising admixing such a substance with a pharmaceutically acceptable excipient, vehicle or carrier, and optionally other ingredients.

20

A substance identified may be peptide or non-peptide in nature. Non-peptide "small molecules" are often preferred for many *in vivo* pharmaceutical uses. Accordingly, a mimetic or mimic of the substance (particularly if a peptide) may be designed for pharmaceutical use. The designing of mimetics to a known pharmaceutically active compound is a known approach to the development of a pharmaceutical based on a "lead" compound. This might be desirable where the active compound is difficult or expensive to synthesize or where it is unsuitable for a particular method of administration, e.g. peptides are unsuitable active agents for oral compositions as they tend to be quickly degraded by proteases in the alimentary canal. Mimetic design, synthesis and testing are generally used to avoid randomly screening large numbers of molecules for a target property.

There are several steps commonly taken in the design of a mimetic from a compound having a given target property. First, the particular parts of the compound that are critical and/or important in determining the target property are determined. In the case of a peptide, this can be done by systematically varying the amino acid residues in the peptide, e.g. by substituting each residue in turn. Alanine scans of peptide are commonly used to refine such peptide motifs. These parts or residues constituting the active region of the compound are known as its "pharmacophore".

Once the pharmacophore has been found, its structure is modeled according to its physical properties, e.g. stereochemistry, bonding, size and/or charge, using data from a range of sources, e.g. spectroscopic techniques, x-ray diffraction data and NMR. Computational analysis, similarity mapping (which models the charge and/or volume of a pharmacophore, rather than the bonding between atoms) and other techniques can be used in this modeling process.

In a variant of this approach, the three-dimensional structure of the ligand and its binding partner are modeled. This can be especially useful where the ligand and/or binding partner change conformation on binding, allowing the model to take account of this in the design of the mimetic.

A template molecule is then selected, onto which chemical groups that mimic the pharmacophore can be grafted. The template molecule and the chemical groups grafted onto it can conveniently be selected so that the mimetic is easy to synthesize, is likely to be pharmacologically acceptable, and does not degrade *in vivo*, while retaining the biological activity of the lead compound. Alternatively, where the mimetic is peptide-based, further stability can be achieved by cyclizing the peptide, increasing its rigidity. The mimetic or mimetics found by this approach can then be screened to see whether they have the target property, or to what extent they exhibit it. Further optimization or modification can then be carried out to arrive at one or more final mimetics for *in vivo* or clinical testing.

The goal of rational drug design is to produce structural analogs of biologically active polypeptides of interest, or of small molecules with which they interact (e.g. agonists, antagonists, inhibitors or enhancers), in order to fashion drugs which are, for example, more active or stable forms of the polypeptide, or which, e.g. enhance or interfere with the

one approach, one first determines the three-dimensional structure of a protein of interest (e.g. FORS) or, for example, of a FORS substrate or FORS-ligand complex, by x-ray crystallography, by computer modeling or most typically, by a combination of approaches.

"Useful" information regarding the structure of a polypeptide may also be gained by

10 modeling based on the structure of homologous proteins. An example of rational drug design is the development of HIV protease inhibitors (Erickson *et al.*, *Science* 249: 527-533, 1990). In addition, peptides (e.g. FORS) are analyzed by an alanine scan (Wells, 1991). In this technique, an amino acid residue is replaced by Ala and its effect on the peptide's activity is determined. Each of the amino acid residues of the peptide is analyzed 15 in this manner to determine the important regions of the peptide.

It is also possible to isolate a target-specific antibody, selected by a functional assay and then to solve its crystal structure. In principle, this approach yields a pharmacophore upon which subsequent drug design can be based. It is possible to bypass protein crystallography altogether by generating anti-idiotypic antibodies (anti-ids) to a functional, pharmacologically active antibody. As a mirror image of a mirror image, the binding site of the anti-ids would be expected to be an analog of the original receptor. The anti-id could then be used to identify and isolate peptides from banks of chemically or biologically produced banks of peptides. Selected peptides would then act as the pharmacophore.

Thus, one may design drugs which, for example, interfere with FORS activity or stability or which act as inhibitors or antagonists of FORS phosphoprotein, or which interact with FORS phosphoprotein or interfere with the phosphorylation of FORS phosphoprotein in

30. For sequences, sufficient amounts of the FORS polypeptide may be made available to perform such analytical studies as x-ray crystallography. In addition, the knowledge of the

FORS protein sequence provided herein will guide those employing computer modeling techniques in place of, or in addition to x-ray crystallography.

According to the present invention, a method is also provided for reducing or down-

regulating *Fors* function in a cell that carries an active *Fors* gene. Removing such a

function should suppress neoplastic growth in the recipient cells. The wild-type *Fors* gene or a part of the gene may be introduced into the cell in a vector such that the gene remains extra-chromosomal. In such a situation, the cell will express the gene from the extra-chromosomal location. Alternatively, it may be integrated into the nuclear genome of the

cell. If a *Fors* gene or a nucleic acid sequence comprising a portion of the *Fors* gene, or a nucleic acid sequence complementary to a *Fors* gene sequence or portion thereof, is introduced and expressed in a cell, it may lead to the down-regulation of the endogenous *Fors* gene present in the cell.

The term "down-regulating" is used in its most generic sense and includes any and all means by which the expression of a gene is reduced, diminished or eliminated, whether at the transcriptional or the post-transcriptional level.

Vectors for introduction of genes both for recombination and for extra-chromosomal maintenance are known in the art and any suitable vector may be used. Methods for introducing DNA into cells such as electroporation, calcium phosphate co-precipitation and viral transduction are known in the art and the choice of method is within the competence of the practitioner.

As generally discussed above, the *Fors* gene or fragment, where applicable, may be employed in gene therapy methods in order to down-regulate gene expression and thereby decrease the amount of the expression products of such genes in cancer cells. Such gene therapy is particularly appropriate for use in both cancerous and pre-cancerous cells, in which the level of FORS polypeptide is absent or diminished compared to normal cells.

One form of gene therapy is carried out according to generally accepted methods, for example, as described by Friedman (In: *Therapy for Genetic Disease*, T. Friedman, Ed.,

Oxford University Press, pp. 105-121, 1991) or Culver (*Gene Therapy: A Primer for*

Physicians, 2nd Ed., Mary Ann Liebert, 1996). Cells from a patient's tumor would be first

5 analyzed by the diagnostic methods described above, to ascertain the production of FORS polypeptide in the tumor cells. A virus or plasmid vector, containing a copy of the *Fors* gene linked to expression control elements is prepared. The vector may be capable of replicating inside the tumor cells. Suitable vectors are known, such as disclosed in U.S.

Patent No. 5,252,479, International Patent Publication No. WO 93/07282 and U.S. Patent

10 No. 5,691,198. The vector is then injected into the patient, either locally at the site of the tumor or systemically (in order to reach any tumor cells that may have metastasized to other sites). If the transfected gene is not permanently incorporated into the genome of

each of the targeted tumor cells, the treatment may have to be repeated periodically. The present invention further contemplates using sense sequences of *Fors* to induce co-

15 suppression or other forms of post transcriptional gene silencing as well as any mechanism involving RNA₂ and/or epigenetic mechanisms to silence gene expression.

Gene transfer systems known in the art may be useful in the practice of the gene therapy methods of the present invention. These include viral and non-viral transfer methods. A

20 number of viruses have been used as gene transfer vectors or as the basis for preparing gene transfer vectors, including papovaviruses (e.g. SV40, Madzak *et al.*, *J. Gen. Virol.*

73: 1533-1536, 1992), adenovirus (Berkner, *Curr. Top. Microbiol. Immunol.* 158: 39-66,

1992; Berkner *et al.*, *BioTechniques* 6: 616-629, 1988; Gorziglia and Kapikian, *J. Virol.*

66: 4407-4412, 1992; Quantin *et al.*, *Proc. Natl. Acad. Sci. USA* 89: 2581-2584, 1992;

25 Rosenfeld *et al.*, *Cell* 68: 143-155, 1992; Wilkinson *et al.*, *Nucleic Acids Res.* 20: 2233-2239, 1992; Stratford-Perricaudet *et al.*, *Hum. Gene Ther.* 1: 241-256, 1990; Schneider *et al.*, *Nature Genetics* 18: 180-183, 1998); vaccinia virus (Moss, *Curr. Top. Microbiol.*

Immunol. 158: 25-38, 1992; Moss, *Proc. Natl. Acad. Sci. USA* 93: 11341-11348, 1996),

adeno-associated virus (Muzyczka, *Curr. Top. Microbiol. Immunol.* 158: 97-129, 1992;

30 Ohi *et al.*, *Gene* 89: 279-282, 1990; Russell and Hirata, *Nature Genetics* 18: 323-328, 1998), herpesviruses including HSV and EBV (Margolskee, *Curr. Top. Microbiol.*

Immunol. 158: 67-95, 1992; Johnson *et al.*, *J. Virol.* 66: 2952-2965, 1992; Fink *et al.*, *Hum. Gene Ther.* 3: 11-19, 1992; Breakefield and Geller, *Mol. Neurobiol.* 1: 339-371,

Neurosci. 19: 265-287, 1996). lentiviruses (Naldini *et al.*, *Science* 272: 263-267, 1996),

5 Sindbis and Semliki Forest virus (Berglund *et al.*, *Biotechnology* 11: 916-920, 1993) and retroviruses of avian (Bandyopadhyay and Temin, *Mol. Cell. Biol.* 4: 749-754, 1984; Petropoulos *et al.*, *J. Virol.* 66: 3391-3397, 1992], murine [Miller, *Curr. Top. Microbiol.*

Immunol. 158: 1-24, 1992; Miller *et al.*, *Mol. Cell. Biol.* 5: 431-437, 1985; Sorge *et al.*,

Mol. Cell. Biol. 4: 1730-1737, 1984; Mann and Baltimore, *J. Virol.* 54: 401-407, 1985;

10 Miller *et al.*, *J. Virol.* 62: 4337-4345, 1988] and human [Shimada *et al.*, *J. Clin. Invest.* 88: 1043-1047, 1991; Helseth *et al.*, *J. Virol.* 64: 2416-2420, 1990; Page *et al.*, *J. Virol.* 64:

5270-5276, 1990; Buchschacher and Panganiban, *J. Virol.* 66: 2731-2739, 1982] origin.

Most human gene therapy protocols have been based on disabled murine retroviruses although adenovirus and adeno-associated virus are also being used.

15

Non-viral gene transfer methods are known in the art such as chemical techniques including calcium phosphate co-precipitation, mechanical techniques, for example, micro-injection, membrane fusion-mediated transfer via liposomes and direct DNA uptake and receptor-mediated DNA transfer. Viral-mediated gene transfer can be combined with direct

20 *in vivo* gene transfer using liposome delivery, allowing one to direct the viral vectors to the tumor cells and not into the surrounding non-dividing cells. Alternatively, the retroviral vector producer cell line can be injected into tumors. Injection of producer cells would then provide a continuous source of vector particles.

25 In an approach which combines biological and physical gene transfer methods, plasmid DNA of any size is combined with a polylysine-conjugated antibody specific to the adenovirus hexon protein and the resulting complex is bound to an adenovirus vector. The trimolecular complex is then used to infect cells. The adenovirus vector permits efficient binding, internalization and degradation of the endosome before the coupled DNA is damaged. For other techniques for the delivery of adenovirus based vectors, see U.S.

30 Patent No. 5,691,198.

Liposome/DNA complexes have been shown to be capable of mediating direct *in vivo* gene transfer. While in standard liposome preparations the gene transfer process is non-specific, localized *in vivo* uptake and expression have been reported in tumor deposits, for example, following direct *in situ* administration.

Expression vectors in the context of gene therapy are meant to include those constructs containing sequences sufficient to express a polynucleotide that has been cloned therein. In viral expression vectors, the construct contains viral sequences sufficient to support packaging of the construct. If the polynucleotide encodes FORS, expression will produce FORS. If the polynucleotide encodes a sense or antisense polynucleotide or a ribozyme or DNAzyme, expression will produce the sense or antisense polynucleotide or ribozyme or DNAzyme. Thus, in this context, expression does not require that a protein product be synthesized. In addition to the polynucleotide cloned into the expression vector, the vector

also contains a promoter functional in eukaryotic cells. The cloned polynucleotide sequence is under control of this promoter. Suitable eukaryotic promoters include those described above. The expression vector may also include sequences, such as selectable markers and other sequences described herein.

The therapy is as follows: patients who carry a *Fors* gene are treated with a gene delivery vehicle such that some or all of their precursor cells receive at least one additional copy of said gene, in sense or antisense and/or combinations thereof, so as to effect interference with the expression of the endogenous *Fors* sequence. In this step, the treated individuals thereby have reduced risk of development of the cancer to the extent that the expression of

the endogenous *Fors* gene has been prevented and/or diminished by the introduction of the additional copies of a part or all of a nucleotide sequence encoding FORS.

Accordingly, in this embodiment, the present invention contemplates genetic constructs such as comprising antisense, sense and ribozyme constructs or RNAi or RNA oligonucleotides. Such genetic compositions are also referred to as DNA vaccination.

compositions and are specifically directed to modulating expression, at the transcriptional or translational levels, of nucleotide sequences encoding a FORS protein.

Accordingly, another aspect of the present invention contemplates a method for the

5 treatment of a patient having cancer, said method comprising administering to said patient, a genetic composition comprising a genetic construct which down-regulates expression of a *Fors* gene encoding FORS.

More particularly, the present invention contemplates a method for the treatment of a
10 patient having cancer, said method comprising administering to said patient, a genetic composition comprising a genetic construct comprising a nucleotide sequence substantially as set forth in SEQ ID NO:4 or a fragment thereof or a nucleotide sequence having at least about 40% similarity to SEQ ID NO:4 after optimal alignment or a nucleotide sequence capable of hybridizing to SEQ ID NO:4 in its complementary form under low stringency

15 conditions.

Reference herein to "expression" includes down-regulating the steps of transcription, translation or both. Particularly preferred genetic constructs are antisense or sense constructs to FORS, which induce co-suppression of the *Fors* gene or induce RNAi-

20 mediated down-regulation of *Fors* mRNA transcript.

In another aspect of the present invention, cells and animals which carry a *Fors* nucleic acid sequence can be used as model systems to study and test for substances which have potential as therapeutic agents. Cells may be isolated, for example, from individuals

25 expressing a *Fors* gene. Alternatively, a cell line may be engineered to carry the *Fors* gene or, in an alternative approach, an aberration in the *Fors* sequence. Mutating or deleting the *Fors* gene or an allele thereof has the ability to reduce or prevent its expression. The term

mutating", and related terms such as "mutate", "mutation" and "mutated", are used in their most generic sense and includes methylation of all or part of the nucleotide

30 sequences, and in particular cytosine or guanine residues, or other events which induces gene silencing.

The term "aberration" encompasses all forms of mutations including deletions, insertions, point mutations and substitutions in the coding and non-coding regions of *Fors*. It also includes changes in methylation patterns of *Fors* or of an allele of *Fors*. Deletions may be

of the entire gene or only a portion of the gene. Point mutations may result in stop codons,

frame-shift mutations or amino acid substitutions. Somatic mutations are those occurring

only in certain tissues, e.g. in the tumor tissue and are not inherited in the germ-line. Germ-

line mutations can be found in any of a body's tissues and are inherited. A *Fors* allele,

which is not deleted (e.g. that found on the sister chromosome to a chromosome carrying a

10 *Fors* deletion), can be screened for other mutations such as insertions, small deletions,

point mutations and changes in methylation pattern. Mutations leading to non-functional

gene products may also lead to decreased prevalence of a cancerous state. Point mutational

events may occur in regulator regions, such as in the promoter of the gene or in an intron

of the gene, leading to loss or diminution of expression of the mRNA. Point mutations may

15 also abolish proper RNA processing leading to loss of expression of the *Fors* gene product

or a decrease in mRNA stability or translation efficiency. Point and other mutations may

also affect proper RNA processing such as intron splicing.

After a test substance is applied to the cells, the neoplastically-transformed phenotype of

20 the cell is determined. Any trait of neoplastically-transformed cells can be assessed,

including anchorage-independent growth, tumorigenicity in nude mice, invasiveness of

cells and growth factor dependence. Assays for each of these traits are known in the art.

Animals for testing therapeutic agents can be selected after mutagenesis of whole animals

25 or after treatment of germ-line cells or zygotes. Such treatments include insertion of *Fors*

genes, usually from a second animal species, and may also include insertion of disrupted

homologous genes. Alternatively, an endogenous *Fors* gene of an animal may be disrupted

by insertion or deletion mutation or other genetic alterations using conventional

techniques. After test substances have been administered to the animals, the growth of

30 tumors must be assessed. If the test substance prevents or suppresses the growth of tumors,

then the test substance is a candidate therapeutic agent for the treatment of the cancers

identified herein. These animal models provide an extremely important testing vehicle for potential therapeutic products.

The identification of the association between the presence of FORS phosphoprotein and

5 cancer permits the early pre-symptomatic screening of individuals to identify those at risk

for developing cancer. To identify such individuals, they are screened for the presence of

FORS, or for *Fors* sequences or the presence of nucleic acid sequence differences from the

normal gene using any suitable technique. Suitable techniques include but are not limited

to, one of the methods hereinbefore described, i.e. fluorescent *in situ* hybridization (FISH),

10 direct DNA sequencing, PFGE analysis, Southern blot analysis, single-stranded

conformation analysis (SSCP), linkage analysis, RNase protection assay, allele specific

oligonucleotide (ASO), dot blot analysis and PCR-SSCP analysis, or DNA/RNA

microchip technology.

15 An alternative strategy is a large scale immunoaffinity purification of *Fors*-biomolecular complexes. The partners in the purified complex can then be eluted off and analysed.

Two-hybrid screening is particularly useful in identifying other members of a biochemical or genetic pathway associated with *Fors*. Two-hybrid screening conveniently uses

20 *Saccharomyces cerevisiae* and *Saccharomyces pombe*. FORS interactions and screens for inhibitors can be carried out using the yeast two-hybrid system, which takes advantage of

transcriptional factors that are composed of two physically separable, functional domains

(Phizicky and Fields, *Microbiol. Rev.* 59(1): 94-123, 1994). The most commonly used is

the yeast GAL4 transcriptional activator consisting of a DNA binding domain and a

25 transcriptional activation domain. Two different cloning vectors are used to generate separate fusions of the GAL4 domains to genes encoding potential binding proteins. The

fusion proteins are co-expressed, targeted to the nucleus and if interactions occur,

activation of a reporter gene (e.g. *lacZ*) produces a detectable phenotype. In the present

case, for example, *S. cerevisiae* is cotransformed with a library or vector expressing a

30 cDNA GAL4 activation domain fusion and a vector expressing a FORS-GAL4 binding domain fusion. If *lacZ* is used as the reporter gene, co-expression of the fusion proteins

will produce a blue color. Small molecules or other candidate compounds which interact with FORS will result in loss of color of the cells. This system can be used to screen for small molecules that inhibit the FORS interaction and, hence, protect the yeast against cell death and to determine the residues in FORS which are involved in their interaction. For example, reference may be made to the yeast two-hybrid systems as disclosed by Munder

et al. (*Appl. Microbiol. Biotechnol.* 52(3): 311-320, 1999) and Young *et al.*, *Nat. Biotechnol.* 16(10): 946-950, 1998). Molecules thus identified by this system are then re-tested in animal cells.

10. The present invention is further described by the following non-limiting Examples.

EXAMPLE 1

Reagents and mice

Reagents

5

Antibodies used were as follows: affinity purified rabbit polyclonal anti-phospho-FKHR (S256) antibody (New England Biolabs); mouse monoclonal anti- α -tubulin antibody (clone B-5-1-2; Sigma); mouse monoclonal anti-ErbB2 antibody (Ab-10; Neomarkers); mouse monoclonal anti-Neu antibody (Ab-3; Calbiochem); mouse monoclonal anti-Flag antibody (Sigma); anti-Pctpl polyclonal rabbit serum. Recombinant human EGF and insulin were purchased from Sigma.

Mice

15 Mouse mammary tumor virus (MMTV)-Neu mice have been previously described (Guy et al. (2000), *supra*. Nulliparous female mice were aged for 8-12 months in standard animal facilities and were sacrificed when tumors developed.

EXAMPLE 2

Preparation of protein lysates

To explore the potential inactivation of the FKHR transcription factor by ErbB receptor signaling, protein lysates prepared from mammary tumors derived from mouse mammary tumor virus (MMTV)-Neu transgenic mice. Whole cell extracts were obtained by

25 solubilizing cells in 1% NEB (50 mM Tris, pH 7.5, 150 mM NaCl, 1% NP40, 1 mM sodium orthovanadate, 10 mM sodium fluoride, 20 mM β -glycerophosphate plus complete protease inhibitors (Roche)). Lysates were clarified by centrifugation at 16,000 x g for 10 min. Protein lysates of tissues were obtained by grinding the tissue to a fine powder under liquid nitrogen and subsequent solubilization in 1% TEB (NEB with substitution of NP40).

30 with Triton X-100). Lysates were homogenized by passing through a 21-gauge needle prior to clarification by centrifugation.

For cytosolic protein extraction, cells were lysed in hypotonic buffer (10 mM Hepes, pH 7.9, 133 mM sorbitol, 0.5 mM sodium fluoride, 0.5 mM β -glycerophosphate plus complete protease inhibitors (Roche)), left to swell on ice for 10 min, homogenized by Douncing and then centrifuged at 800 $\times g$ for 10 min. The pellet was washed with hypotonic buffer and the supernatants were combined to yield the cytosolic fraction.

EXAMPLE 3

A tumor-specific 35 kDa protein cross-reacts with a phosphospecific

FKHR antibody

Mammary tumor lysates were analyzed by Western blotting, using an antibody that specifically recognizes FKHR phosphorylated on serine 256 (Figure 1A).

The proteins were blotted onto polyvinylidene difluoride membranes (Millipore). After blocking with 20% v/v horse serum (Hunter) in PBS containing 0.1% v/v Tween-20, filters were probed with specific antibodies. Proteins were visualized with peroxidase-coupled secondary antibody using the ECL detection system (Amersham). Stripping of membranes was performed in SDS buffer (62.5 mM Tris, pH 6.8, 2% v/v SDS, 100 mM β -mercaptoethanol) for 30 min at 60°C. Membranes were then re-probed with the indicated antibodies.

No signal corresponding to FKHR was detected in tumor or adjacent mammary tissue, reflecting the low level of FKHR expression. Interestingly, the phosphospecific FKHR antibody strongly cross-reacted with a 35 kD protein that was present in tumor but not in adjacent or normal mammary tissue, as shown in Figure 1. Western blotting with an anti-Neu antibody confirmed over-expression Neu in these tumors.

Further analysis of several breast epithelial cell lines revealed that the 35kD protein was absent in the immortalized breast epithelial cell lines HBL100 and 184, but could be

detected in the majority of transformed cell lines (refer to Example 9, below, and to Figure 5C).

Since no FoxO family members corresponding to this molecular weight had been described, it was hypothesized that the 35 kD protein might represent a novel FKHR-related protein. This protein was likely to be phosphorylated on a serine residue lying in a conserved sequence context, given the specificity of the FKHR-specific antibody.

EXAMPLE 4

10. *Purification of the 35 kD protein*

In order to identify the protein cross-reacting with the phospho-FKHR antibody, an immunoprecipitation with this antibody using SKBR3 cell lysate was performed.

15. For immunoprecipitations, equal amounts of protein were incubated with specific antibodies for 2 h on ice. Immune complexes were collected with protein G-Sepharose (Pharmacia) and washed three times with 1% NEB. For phosphorylation analysis, immune complexes were further washed with 10 mM Tris, pH 8, 100 mM NaCl, before being incubated in the same buffer with 5 units of alkaline phosphatase (Roche) for 45 min at 20°C.

20. Precipitated proteins were released by boiling in sample buffer and were subjected to sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis (PAGE) using 4-20% gradient gels (Novex).

25. While the antibody readily detected the 35 kDa protein by Western blotting, it failed to immunoprecipitate the protein. A multi-step biochemical purification strategy was therefore devised, based on parameters such as isoelectric focusing point, hydrophobicity and molecular weight of the protein. Since the 35 kD protein was demonstrated to be cytosolic, protein lysates from SKBR3 cells were prepared by hypotonic lysis using conditions that are compatible with isoelectric focusing (IEF). An analytical sample of

30. SKBR3 cytosol was initially analyzed by free flow electrophoresis (FFE), a liquid based isoelectric focusing method.

FFE was essentially performed as described in Hoffmann *et al.*, *Proteomics* 1: 807-818, 2001, using the Octopus apparatus. The IEF running buffer was aqueous 0.2% w/v HPMC (hydroxypropyl methyl cellulose) and 0.2% w/v carrier ampholytes (Servalyte pH 3-10).

Electrode solutions were 100 mM H₃PO₄ (anode) and 50 mM NaOH (cathode); the counter flow solution (0.7 l/min) was 0.2% HPMC containing 0.02 M L-arginine and 0.02 M L-lysine. For preparative separations, the sample was diluted to a final concentration of approximately 0.25 mg protein per ml. Electrophoresis was performed at 4°C with a flow rate of 1.4 ml/min and a constant voltage of 1250 V.

10

This continuous mode of isoelectric focusing is especially advantageous for protein purification when large volumes of cell lysate are required. As shown in Figure 2A, Western blotting of individual fractions using the phospho-FKHR antibody revealed the presence of two protein bands with distinct isoelectric focusing points, corresponding to pH 5.6 and pH 6. This shift may reflect differential phosphorylation.

To test whether the 35 kD protein could be effectively separated by reverse phase HPLC, SKBR3 cytosol was subjected to RP-HPLC. The 35 kD protein was found to elute in specific fractions, as shown in Figure 2B.

20

For preparative purification of the 35 kD protein, 275 mg of cytosolic protein was applied to FFE followed by RP-HPLC. Fractions containing the 35 kD protein were identified by Western blotting using the phospho-FKHR antibody, then pooled (7 mg) and subjected to RP-HPLC. HPLC fractions containing the 35 kD protein were pooled and precipitated by addition of 0.5% w/v deoxycholate and 15% v/v TCA plus two volumes of acetone at 20°C. After centrifugation at 16,000 x g for 15 min, the protein pellet was washed with acetone, briefly left to dry and resuspended in sample buffer. A large 10% w/v gel was poured according to Laemmli and electrophoresis was performed at 150 V for 6 hours. The gel was fixed and stained with Coomassie Phast-gel Blue R (Pharmacia, UK). (Figure 2C).

30

The bands migrating at approximately 35 kD were excised, digested *in situ* with trypsin and analyzed by tandem mass spectrometry. All peptides from band #1 matched an entry in the Trembl database, Q9Y365, a predicted human protein based on a comparative screen of the *C. elegans* proteome with human est nucleotide databases (Lai *et al.*, *Genome Research* 10: 703-713, 2000). Alignment of this sequence with the FKHR protein failed to identify a forkhead domain but instead identified a region in Q9Y365 that was highly similar to the sequence surrounding serine 256 to which the phospho-FKHR antibody had been raised (Figure 2D). Most importantly, this sequence in Q9Y365 contained a serine that (i) aligned with S256 in FKHR and (ii) obtained a high score in the NetPhos phosphorylation prediction program. It, therefore, appeared likely that this protein, when phosphorylated on this serine residue, would cross-react with the FKHR-specific antibody.

EXAMPLE 5

Cloning and expression analysis of the 35 kD protein, FORS

Sequence analysis of Q9Y365 predicted a molecular weight of 40 kD and a pI of 8.55, higher than the experimentally observed values of the 35 kD protein. No sequence coverage of the first 71 amino acids was obtained, suggesting that translation was initiated from the methionine at position 68, giving rise to a protein of 291 amino acids with a theoretical mass of 33 kD and a pI of 6.7. These calculations do not take into account the presence of phosphorylation sites, which would render the protein more acidic (Figure 3A) and would decrease the electrophoretic mobility in SDS-PAGE.

Full-length cDNA encoding a 33 kD protein product was generated by RT-PCR using RNA derived from SKBR3 cells. Total RNA was extracted from SKBR3 cells using RNazol (Tel-Test). First strand cDNA synthesis was performed and *Fors* cDNA was amplified by PCR using primers based on the CGI-52 sequence (Accession No. AF151810). *Fors* cDNA was cloned into HA-pcDNA3.0, Flag-pEF_rPGKpuro and pBabePuro for expression in mammalian cells. An HA or Flag tag was incorporated at the N-terminus within the pcDNA3.0 or pEF-1_αrev expression vectors, respectively, to facilitate recognition.

Remarkably, transient expression of the HA-tagged expression plasmid in 293T cells gave rise to a protein that was detected by the phospho-FKHR antibody (Figure 3B). The slight difference in size compared to the endogenous protein is most likely due to the presence of the tag. Recognition of this protein was phosphorylation-dependent, since treatment of immunoprecipitated Flag-tagged protein with alkaline phosphatase abrogated the cross-reactivity. This suggests that serine 259 in the 35 kD protein is indeed phosphorylated. This protein was, therefore, termed FORS (forkhead related serine).

Although the existence of a long human FORS protein as predicted by Lai *et al.* (2000) *supra* cannot be ruled out, Pctp2, the mouse homolog of FORS, was cloned as a 291 amino acid protein from a mouse testis library. The mouse sequence does not indicate the presence of larger protein since there is no open reading frame encoding an amino-terminal extension, distinct from that observed in the human sequence.

EXAMPLE 6

Northern analysis of FORS mRNA

Poly(A)⁺ RNA was isolated from breast epithelial cell lines and Northern analysis was performed as described (Visvader, *EMBO J.* 11: 4557-4564, 1991). Briefly, 4 µg of poly(A)⁺ RNA was fractionated on 1% w/v agarose-formaldehyde gel, transferred to Hybond N⁺ (Amersham Pharmacia Biotech), and hybridized with the following cDNA probes: Fors cDNA, encompassing the entire 876 bp coding region or residues 769-876; ErbB2 cDNA (residues 1-228); EGFR cDNA (residues 1-293) or GAPDH cDNA. Human multiple poly(A)⁺ RNA tissue Northern blots (Clontech Laboratories, Inc.) were hybridized with a *Fors* cDNA probe.

Northern analysis of *Fors* mRNA from a variety of human organs revealed high levels of a 1.4 kb transcript in liver, heart, skeletal muscle and kidney. While a faint signal was detected in placenta, organs such as brain, colon, thymus, spleen, small intestine, lung and PBL cells lacked *Fors* mRNA.

EXAMPLE 7***Co-expression of FORS and ErbB2 occurs at high levels in breast cancer cell lines***

FORS levels were originally found to be abundant in tumors from Neu transgenic mice and in breast carcinoma cell lines using an antibody that recognizes the protein in a phosphorylation-dependent manner. To determine whether *Fors* up-regulation was occurring at the RNA level and whether it correlated with over-expression of ErbB2,

10 Northern analysis was performed, as described in Example 6, above, on a panel of breast epithelial cell lines (Figure 4A).

High levels of *Fors* were found in the cell lines that were previously shown to express phosphorylated FORS protein, indicating over-expression at the transcriptional level. *Fors* expression was barely detectable in both human and mouse immortalized cell lines (184,

15 HBL100, Scp2, Eph4 and HC11). Interestingly, all cell lines that over-expressed ErbB2 mRNA were established to have higher *Fors* levels. *Fors* over-expression, however, was also noted in cell lines without a concomitant increase in ErbB2 expression.

20 An expression survey of human colon carcinoma cell lines suggested that over-expression of *Fors* might also be a feature of this tumor type (Figure 4B). Several cell lines expressed *Fors* to a level that was comparable to that seen in SKBR3 cells. However, there was no correlation between *Fors* and EGFR mRNA.

EXAMPLE 8***Culture of cell lines***

Breast epithelial cell lines were maintained in RPMI containing 10% v/v fetal bovine serum (FBS) (CSL) and 1 µg/ml insulin with the exception of MCF10A cells that were grown in DME HAM supplemented with 10% µ FBS, 10 ng/ml EGF, 5 µg/ml insulin and 1 µM dexamethasone.

293T, NIH3T3 and HER14 (NIH3T3 transfected with the human EGFR) and Bosc cell lines were grown in DME medium containing 10% v/v FBS. NIH3T3 Fors and HER14 Fors were generated by stable introduction of a pBabe retrovirus encoding HA-tagged Fors using Bosc packaging cells and selection with 1 µg/ml puromycin (Sigma).

For transient transfections, 293T cells were transfected with Fugene reagent (Roche) according to the manufacturer's instructions.

EXAMPLE 9

Generation of FORS-specific antibodies

Database searches identified the presence of a Start domain in FORS (amino acid 21-226), a phospholipid binding domain first noted in the steroidogenic acute regulatory protein (Pctp) or STAR. The Start domain of FORS is 28% identical and 49% similar to that of human Pctp (phosphatidylcholine transfer protein), a 214 amino acid protein which consists almost entirely of the Start domain. Unlike Pctp, FORS has a 65 amino acid carboxyterminal extension (Figure 5A).

To generate an antibody specific for FORS, rabbits were immunized with a keyhole limpet hemocyanin (KLH; Sigma)-coupled peptide encompassing amino acids 265-277 at the C-terminus downstream of the Start domain. The peptide ESAVAESREERMG (SEQ ID NO:1) corresponding to amino acids 265-277 of FORS was selected, based on antigenicity and surface availability predictions and synthesized with an additional aminoterminal cysteine (Auspep) for coupling to KLH. In brief, KLH was cross-linked with N-Succinimidyl 3-(2-pyridyldithio)propionate (Pierce) and added to peptide that had been reduced and purified with SepPak columns (Waters). Two rabbits (# 419 and 420) were injected subcutaneously with 200 µg peptide in complete adjuvants and boosted in 2 weekly intervals. Bleeds were tested by ELISA and Western blotting. Antibody purification from rabbit sera was performed with peptide that had been covalently coupled to Sulfolink coupling gel (Pierce) following the manufacturer's instructions. Elution was

carried out with 100 mM glycine, pH 2.7 and antibody-containing fractions were pooled and dialyzed against PBS.

EXAMPLE 10

Localization of FORS in breast epithelial cells

Upon affinity purification, both antibodies were found to specifically recognize human FORS protein (Figure 5B). Immunoblotting of breast epithelial cell lines confirmed that over-expression of phosphorylated FORS protein correlates with ErbB2 status in many cases (Figure 5C).

Immunofluorescence of MCF7 cells was undertaken, with a FORS-specific antibody, using confocal microscopy. Cells were plated onto cover-slips in 6-well dishes 24 hours prior to immunostaining. Cells were fixed with 4% v/v paraformaldehyde in PBS for 10 min,

permeabilized with PBS-T (PBS containing 0.2 Triton X-100) and then blocked (5% goat serum (Hunter) in PBS-T) for 30 min. Cover-slips were incubated for 1 hour with affinity purified FORS-specific polyclonal antibody (#420) diluted in blocking solution. After washing with PBS-T, cover-slips were incubated with anti-rabbit secondary antibody conjugated to fluorescein isothiocyanate (The Jackson Laboratory). Cells were counterstained with 1 µg/ml Bis-benzimide (Sigma) and cover-slips were then mounted onto slides with fluorescent mounting medium (Dako Corp., Carpinteria, CA). Cells were examined using a Leica Corp. TCS-4D confocal microscope.

Results revealed punctate staining in the cytoplasm and some staining in the nucleus.

Interestingly, FORS also appeared to be concentrated at the boundaries of cell clusters (Figure 5B). Scansite sequence analysis of FORS suggests that the carboxyterminus may harbor a PDZ domain recognition motif. It will thus be interesting to determine the intracellular compartment to which FORS localizes and whether its localization is controlled by PDZ interactions.

EXAMPLE 11

Fors cooperates with ErbB1 in cellular transformation

To investigate the effect of FORS over-expression on cell proliferation, NIH3T3 and HER14 cells stably over-expressing *Fors* were generated by retroviral infection. The HER14 line represents NIH3T3 cells stably expressing the EGFR. Parental NIH3T3 and HER14 cells lack FORS, determined by Western blotting using an anti-Pctp2 antibody which recognizes both the mouse and human protein (Figure 6A).

10 *Fors* over-expression did not appear to alter the morphology of either NIH3T3 or HER14 cells. Growth was assessed by MTS assays, carried out by plating 2000 cells per well (96 well plate) in 100 µl culture medium containing 10% or 0.5% v/v FBS. The absorbance at 490 nm was determined with an Elisa plate reader after addition of 20 µl MTS reagent (Promega) and incubation at 37°C for 2 hours. Growth in normal and limiting serum 15 conditions was not affected by expression of FORS (Figure 6B). Furthermore, no difference in the growth rate was observed when EGF was added to HER14 *Fors* cells grown in 0.5% serum, compared to HER14 Puro control cells. However, *Fors* expression was found to enhance anchorage-independent growth of both NIH3T3 and HER14 cells.

20 Growth in soft agar was also assessed, as follows. 5 x 10⁴ for NIH3T3 lines and 2.5 x 10³ for HER14 lines were plated in duplicate or triplicate in 6 well plates in 2 ml culture medium supplemented with 0.35% Difco agar overlaying a 2 ml 0.7% bottom agar. For stimulation of the EGFR in HER14 lines, 10 ng/ml EGF was added to the top agar. The cells were incubated for four weeks and re-fed on a weekly basis with 300 µl culture 25 medium (with or without EGF for HER14 lines). Cells were stained by addition of 400 µl PBS containing 0.5 mg nitroblue tetrazolium (Sigma) for 24 hours before photographing using a Nikon SMZ-U microscope connected to an Axiocam digital camera (Zeiss). Photographs were analyzed using ImageJ software.

30 Introduction of *Fors* into NIH3T3 cells allowed outgrowth of few small colonies when 50,000 cells were plated per well (Figure 7A). HER14 cells are capable of growing in soft

agar and colony number and size can be increased by the addition of EGF. Expression of FORS in these cells doubled the number of colonies larger than 50 μ m in diameter and colonies also reached a larger size (Figures 7B and 7C). Taken together, these results suggest that FORS specifically affects anchorage independent proliferation, a crucial feature of cellular transformation, and that it functions synergistically with the EGFR.

NIH3T3 cells expressing *Fors* are tested for an ability to form tumors in nude mice. Furthermore, HER14 *Fors* cells are examined to ascertain whether they have a growth advantage *in vivo* compared HER14 Puro control cells.

10

EXAMPLE 12

Fors is over-expressed in primary human breast cancers

A polyclonal antibody, highly specific for FORS by Western blotting and 15 immunofluorescence, has been generated. Using this antibody, staining of histological sections of human breast tumors addresses the question of whether FORS up-regulation is linked to tumor grade and useful as a prognostic marker. These histological examinations of the FORS protein are extended to other tumor types, such as colon carcinoma. Present results indicate that FORS up-regulation may be of significance in a subset of human colon 20 carcinoma cell lines. Moreover, screening of a cDNA expression library derived from a human colon tumor patient with autologous serum identified auto-antibodies raised against FORS (Scanlan *et al.*, *Int. J. Cancer* 75: 652-658, 1998), indicating that FORS may be a target for antitumoral immune response.

25 Those skilled in the art will appreciate that the invention described herein is susceptible to variations and modifications other than those specifically described. It is to be understood that the invention includes all such variations and modifications. The invention also includes all of the steps, features, compositions and compounds referred to or indicated in this specification, individually or collectively, and any and all combinations of any two or 30 more of said steps or features.

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- BLACK BORDERS**
- IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- FADED TEXT OR DRAWING**
- BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- SKEWED/SLANTED IMAGES**
- COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- GRAY SCALE DOCUMENTS**
- LINES OR MARKS ON ORIGINAL DOCUMENT**
- REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
